Abstract The mammal family Tenrecidae (Afrotheria: Afrosoricida) is endemic to Madagascar. Here we present the conservation priorities for the 31 species of tenrec that were assessed or reassessed in 2015–2016 for the IUCN Red List of Threatened Species. Six species (19.4%) were found to be threatened (4 Vulnerable, 2 Endangered) and one species was categorized as Data Deficient. The primary threat to tenrecs is habitat loss, mostly as a result of slash-

and-burn agriculture, but some species are also threatened by hunting and incidental capture in fishing traps. In the longer term, climate change is expected to alter tenrec habitats and ranges. However, the lack of data for most tenrecs on population size, ecology and distribution, together with frequent changes in taxonomy (with many cryptic species being discovered based on genetic analyses) and the poorly understood impact of bushmeat hunting on spiny species (Tenrecinae), hinders conservation planning. Priority conservation actions are presented for Madagascar's tenrecs for the first time since 1990 and focus on conserving forest habitat (especially through improved management of protected areas) and filling essential knowledge gaps. Tenrec research, monitoring and conservation should be integrated into broader sustainable development objectives and programmes targeting higher profile species, such as lemurs, if we are to see an improvement in the conservation status of tenrecs in the near future.

Introduction

The mammal family Tenrecidae (Supercohort Afrotheria: Order Afrosoricida), endemic to the Indian Ocean island of Madagascar, contains 31 currently recognized extant species in three subfamilies: the Geogalinae (1 species), Oryzorictinae (25) and Tenrecinae (5). The tailless tenrec *Tenrec ecaudatus* has been introduced by humans to neighbouring archipelagos. Tenrecs exhibit a diverse array of body sizes and morphological, behavioural, physiological and ecological specializations, representing an adaptive radiation that is a model for evolutionary research (e.g. Eisenberg & Gould, 1970; Stephenson & Racey, 1995; Olson & Goodman, 2003; Everson et al., 2016).

Most tenrecs are dependent on forest habitats, and, with Madagascar having lost c. 40% of its forests in the last 50 years (Harper et al., 2007), the conservation status of many species is of concern. If the biodiversity of the country is to be conserved, its fauna and flora need to be assessed regularly and relevant conservation strategies must be developed.

The IUCN Red List of Threatened Species (IUCN, 2018; hereafter the IUCN Red List) is the most widely used tool for assessing the conservation status of species. Any new data for the IUCN Red List not only advances the knowledge needed to define conservation action but also provides countries with data against which to report on their environmental goals, such as those defined in the Aichi Targets and Sustainable Development Goals (Brooks et al., 2015).

Here we review the current conservation status of the Tenrecidae, as defined in the last species assessments conducted for the IUCN Red List in 2015–2016, with the aim of identifying trends in extinction risk, habitat needs and threats. We also identify conservation priorities to ensure a future for these poorly known small mammals. This is the first time the conservation needs of tenrecs have been compiled for almost 3 decades (Nicoll & Rathbun, 1990).

Methods

We conducted this review in three stages. Firstly, during 2015–2016, we reassessed the status of all species in the Tenrecidae for the IUCN Red List (IUCN, 2018). Grandidier's shrew tenrec *Microgale grandidieri* had not been assessed before as it was described only in 2009 (Olson et al., 2009), subsequent to the last comprehensive assessment of all mammals (Schipper et al., 2008). Using information available for each species from the literature, such as the latest georeferenced distribution data collated by Goodman et al. (2013) and past and recent assessments of threats to and conservation priorities for tenrecs (e.g. Nicoll & Rathbun, 1990; Stephenson, 1993a,b, 1994, 1995a; Stephenson et al., 1994; Jenkins et al., 2011; Nicoll & Ratsifandrihamanana, 2014), and based on the assessors' knowledge, we collated data on geographical range (including area of occupancy or extent of occurrence), estimated population trends (or relative abundance), habitat use, life history traits, use and trade, threats, conservation actions currently in place and conservation actions needed. We then used this information to assess the risk of extinction for each species by applying the IUCN Red List categories and criteria (IUCN, 2012) which allowed us to assign each species to a category of threat ranging through Extinct, Extinct in the Wild, Critically Endangered, Endangered, Vulnerable, Near Threatened and Least Concern. A species

can also be considered Data Deficient 'when there is inadequate information to make a direct or indirect assessment of its risk of extinction' (IUCN, 2012). During the second stage of the review, a workshop was held in April 2015 by the Tenrec Section of the IUCN Species Survival Commission (SSC) Afrotheria Specialist Group, associated with the 12th African Small Mammals Symposium in Mantasoa, Madagascar, to review the data collected and the draft assessments. At that time, we also developed conservation priorities based on identified threats (as per the Open Standards for the Practice of Conservation; Conservation Measures Partnership, 2013). During the third stage, we conducted a literature review on broader conservation issues in Madagascar, to refine and finalize the priorities.

There is ongoing discussion about tenrec systematics (e.g. Poux et al., 2008; Asher & Helgen, 2010; Everson et al., 2016). To ensure we consider the latest recognized taxonomies, here we treat the three species of otter-shrew on mainland Africa (once considered tenrecs) as a separate family, the Potamogalidae (following Everson et al., 2016). We similarly follow those authors' synonymization of the genus *Limnogale* with *Microgale* (see also Asher & Helgen, 2010) and placement of the large-bodied shrew tenrecs *Microgale dobsoni* and *Microgale talazaci* in the genus *Nesogale*.

Extinction risk

Of the 31 species assessed, 24 (77.4%) were categorized as Least Concern, one species (3.2%) as Data Deficient (*Oryzorictes tetradactylus*), four species (12.9%) as Vulnerable (*Microgale dryas*, *Microgale mergulus*, *Microgale monticola*, *Microgale nasoloi*) and two (6.5%) as Endangered (*Microgale jenkinsae*, *Microgale jobihely*; Table 1). In this assessment, all species were placed in the same Red List category as in previous assessments in 1996 and 2008 (Hoffmann et al., 2011). The status of some species has remained constant for much longer. For example, the aquatic tenrec *M. mergulus* was also considered Vulnerable 30 years ago when it was first assessed. This consistency across assessments probably reflects the lack of concrete data on the impact of continued forest loss on population numbers. Grandidier's shrew tenrec *M. grandidieri*, which had not previously been assessed, was categorized as Least Concern.

Five of the six threatened species were categorized as Vulnerable or Endangered under criterion B, in which status is determined primarily on geographical range and number of locations. The two Endangered species had an extent of occurrence (EOO) < 5,000 km² and were both known from less than five sites: Jenkins' shrew tenrec *M. jenkinsae* is known only from Mikea National Park (Goodman & Soarimalala, 2004; Stephenson et al., 2016c) and there are

TABLE 1 Malagasy tenrecs categorized as threatened or Data Deficient following the IUCN Red List assessment of 2015–2016. The remaining 24 of the 31 Malagasy species assessed were considered Least Concern. Note that in the IUCN Red List, the aquatic tenrec was assessed as *Limnogale mergulus*, whereas the IUCN SSC Afrotheria Specialist Group now recognizes this as a synonym of *Microgale*. For full details on each species, including data sources, see Stephenson et al. (2016a,b,c,d,e,f,g). For species assessed and considered Least Concern, see IUCN Afrotheria Specialist Group (2018).

Species	Red List status ¹ & criteria	Justification for listing			
		AOO/EOO ²	Locations	Habitat	Offtake ³
Dryad shrew tenrec <i>Microgale dryas</i>	VU B1ab(iii)	EOO 7,911 km ² ($< 20,000$ km ²)	9	Declining	No
Jenkins' shrew tenrec <i>Microgale jenkinsae</i>	EN B1ab(iii)	EOO $< 2,000$ km ² ($< 5,000$ km ²)	1	Declining	No
Northern shrew tenrec <i>Microgale jobihely</i>	EN B1ab(iii)	EOO $< 5,000$ km ²	3 (2 populations)	Declining	No
Aquatic tenrec <i>Microgale mergulus</i>	VU B2ab(ii, iii)	AOO $< 2,000$ km ²	10	Declining	Yes
Montane shrew tenrec <i>Microgale monticola</i>	VU D2	EOO 3,496 km ² ($< 5,000$ km ²)	4	Declining	No
Nasolo's shrew tenrec <i>Microgale nasoloi</i>	VU B1ab(iii)	EOO 10,183 km ² ($< 20,000$ km ²)	4	Declining	No
Four-toed mole tenrec <i>Oryzorictes tetradactylus</i>	DD	Most specimens caught > 100 years ago		Unknown	No

¹VU, Vulnerable; EN, Endangered; DD, Data Deficient.

²Data on area of occupancy (AOO) and extent of occurrence (EOO) were derived from Goodman et al. (2013).

³Offtake refers to direct capture (intentional or unintentional).

only two widely disjunct populations of the northern shrew tenrec *M. jobihely* (Soarimalala et al., 2010; Stephenson et al., 2016d). All four Vulnerable species are known from 10 sites or less, of which three had an EOO $< 20,000$ km² (and were categorized under criterion B1), and one, the aquatic tenrec *M. mergulus*, which lives exclusively in riverine habitat, had an estimated area of occupancy (AOO) of $< 2,000$ km² and was categorized under criterion B2. The montane shrew tenrec *M. monticola* was categorized as Vulnerable under criterion D (which relates to small and very restricted populations), as it is known from only four sites in an EOO of $< 20,000$ km².

A single species, the four-toed mole tenrec *Oryzorictes tetradactylus*, was considered Data Deficient because there is no recent information on its EOO, population and threats (Stephenson et al., 2016g), which meant we could not assess its status. Like many fossorial and semi-fossorial species, mole tenrecs are difficult to trap, and the majority of records of this species are from more than a century ago.

Amongst the species categorized as Least Concern, the highland streaked tenrec *Hemicentetes nigriceps* has a

relatively small EOO of 15,232 km² (Goodman et al., 2013). However, it is assumed that its relatively high local abundance and apparent tolerance of anthropogenic habitats mean that the species does not meet any of the subcriteria for a threatened category (Stephenson et al., 2016h). Most species assessed as Least Concern are probably declining because of continued habitat loss across Madagascar, and their status will need to be monitored.

Habitats

Subtropical/tropical moist lowland forest and subtropical/tropical moist montane forest are the habitat types (as defined by IUCN, 2018) with the highest number of tenrec species and whose conservation will ensure the greatest tenrec diversity (Table 2). However, western dry forests are key for some species, especially the threatened Jenkins' shrew tenrec and Nasolo's shrew tenrec (Fig. 1; Goodman & Soarimalala, 2004; Soarimalala & Goodman, 2008). Riparian habitats are important for the aquatic tenrec (Plate 1), and the four-toed mole tenrec is known from montane ericoid thicket (categorized by IUCN as high-altitude grass or shrublands).

TABLE 2 Habitat types important for tenrec species in Madagascar. Habitat categories are derived from the IUCN Red List of Threatened Species (IUCN 2018).

Habitat types (IUCN Classification System)		No. of tenrec species	Threatened or Data Deficient tenrec species in the habitat
1.5	Subtropical/tropical dry forest	6	<i>Microgale jenkinsae</i> <i>Microgale nasoloi</i>
1.6	Subtropical/tropical moist lowland forest	20	<i>Microgale mergulus</i> <i>Microgale dryas</i>
1.9	Subtropical/tropical moist montane forest	20	<i>Microgale jobihely</i> <i>Microgale monticola</i> <i>Oryzorictes tetradactylus</i>
3.5	Subtropical/tropical dry shrubland	2	<i>Microgale jenkinsae</i>
3.7	Subtropical/tropical high altitude shrubland	1	<i>Oryzorictes tetradactylus</i>
4.7	Subtropical/tropical high altitude grassland	1	<i>Oryzorictes tetradactylus</i>
5.1	Permanent rivers, streams, creeks	1	<i>Microgale mergulus</i>
5.4	Bogs, marshes, swamps, fens, peatlands	1	

Some species, such as the Hova mole tenrec *Oryzorictes hova*, the tailless tenrec and the lowland streaked tenrec *Hemicentetes semispinosus*, tolerate human-altered habitats, such as gardens or rice fields, to an unknown extent.

Threats

The main threats facing tenrecs are habitat loss, fragmentation and degradation (77% of species) and hunting for subsistence or bushmeat trade (33% of species). Incidental capture (bycatch) in fishnets and traps is a threat to the aquatic tenrec. Climate change is considered a long-term threat to most species. Lack of knowledge curtails our ability to assess threats and species status and therefore hinders our ability to identify conservation priorities accurately.

Deforestation rates are estimated to range from 0.93 to 2.33% per year for the humid forest and from 0.46 to 1.17% per year for dry forest (Grinand et al., 2013). The main cause of forest loss is traditional slash-and-burn agriculture, as well as commercial logging for timber, mining of precious metals and semi-precious gems (such as sapphires), uncontrolled fires and infrastructure development. Dry deciduous forest is increasingly cleared for cash crops such as peanuts for foreign markets (NR, pers. obs.).

Five of the six threatened tenrec species are dependent on native forest habitats, and the aquatic tenrec inhabits clear, free-flowing streams with stony beds that are threatened by the siltation resulting from forest loss. Although the coverage of Madagascar's protected area network quadrupled since 2003 (Gardner et al., 2018), and all tenrec species occur in at least one protected area (Nicoll & Ratsifandrihamanana, 2014), deforestation is occurring in many parks and reserves where law enforcement capacity

is low (Allnutt et al., 2013; Eklund et al., 2016; Gardner et al., 2018).

Spiny tenrecs of the subfamily Tenrecinae are hunted across most of the island, within and outside protected areas, and the meat is consumed for subsistence or sold in local restaurants and urban markets (Garcia & Goodman, 2003; Randrianandrianina et al., 2010; Jenkins et al., 2011; Reuter et al., 2016). The tailless tenrec, which is widespread and occurs in many habitats, is the most commonly consumed species. It is legal to hunt tenrecs in Madagascar (e.g. the tailless tenrec is on the game species list in decree 2006-400), even though the government acknowledges that hunting and the bushmeat trade are a significant threat to these mammals (Rabarison et al., 2016). The level of offtake is uncertain but can be significant locally. For example, hunters catch up to 40 tenrecs per hunt (Randrianandrianina et al., 2010) and 1,324–5,824 tenrecs are consumed per year in the city of Antsiranana (Reuter & Sewall, 2016). Until the impact of hunting on population levels is better understood, all exploited species were categorized as Least Concern.

Climate change is a direct threat to biodiversity and a driver of other threats (Hannah et al., 2008). Madagascar ranks third in the world for extreme climate risk (Verisk Maplecroft, 2012). Climate change is predicted to lead to altered habitats and niche availability and changes in species ranges, as demonstrated in lemurs where the range of 60% of species is expected to decline in 70 years (Brown & Yoder, 2015). Tenrec habitat, species distribution and abundance are similarly expected to change, but no projections have been made on the likely extent of the change. Because species restricted to mountains have less scope to disperse, montane forest-dwelling species of shrew tenrecs could be most vulnerable to climate change.

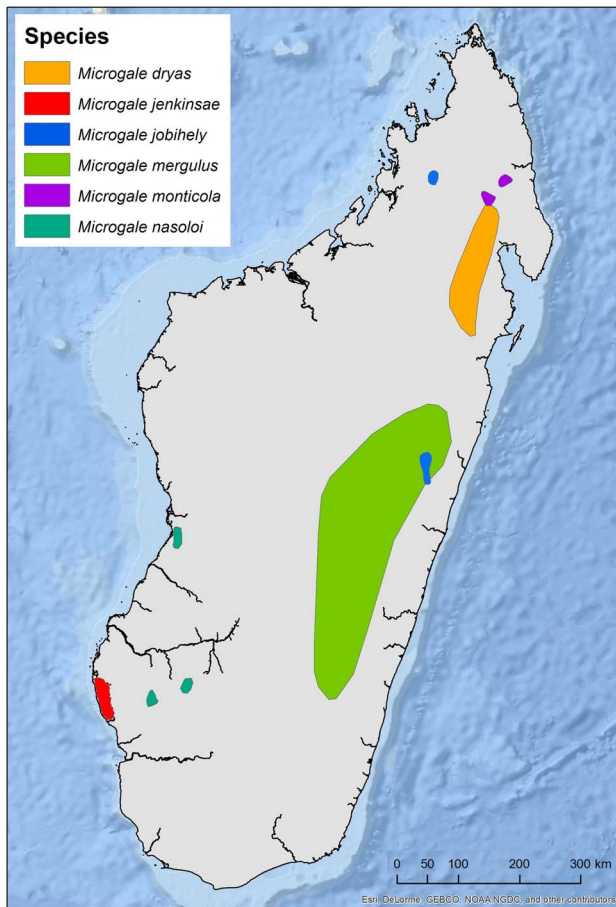

FIG. 1 Distribution map of threatened tenrecs in Madagascar, showing the known key areas for tenrec habitat (map courtesy of Natalia Ocampo; data from IUCN, 2018, based on Goodman et al., 2013).

Madagascar's environment is now more degraded than 25 years ago (Freudenberger, 2010; Goodman et al., in press). Pressures on natural resources are increasing, largely because the human population has risen from 5.1 million in 1960 to 24.9 million in 2016 (World Bank, 2018). The national economy is weak (gross domestic product has halved since 1960) and the World Bank (2016) calculates that 78% of the population live below the international poverty line (USD 1.90 per person per day), making it one of the 10 poorest countries in the world. Most Malagasy rely on the direct use of natural resources for their livelihoods, which affects many mammals and their habitats.

All threatened tenrec species are known from only a few individuals captured at 10 or fewer locations, making it hard to determine accurately their distribution, abundance, habitat preferences, or population trends. There have been few ecological studies and little information exists on tenrec behaviour. Few Malagasy protected areas have monitoring schemes in place. In addition, tenrec taxonomy is changing regularly as a result of ongoing genetic analyses and

PLATE 1 The aquatic tenrec *Microgale mergulus* is categorized as Vulnerable because of its restricted number of known sites (10) and limited area of occupancy (< 2,000 km²). © P.J. Stephenson.

morphometric studies of museum specimens. The genus *Microgale* has been the subject of taxonomic revisions and reorganization (e.g. Stephenson 1995b; Everson et al., 2016), five new species were described in the last 20 years and numerous new species are expected in the next two years (Everson et al., 2018; LEO, unpubl. data). Other key data gaps include the impacts of hunting on spiny tenrecs and the relative dependence of species on intact forest habitats.

Conservation priorities

Our review suggests conservation efforts for tenrecs need to focus primarily on the seven species identified as threatened or Data Deficient in the IUCN Red List (Table 1). There is a need to improve the management and protection of key habitats and enhance our knowledge base.

Priorities for tenrec habitat conservation

The main action required to conserve threatened tenrecs is the protection of adequately sized, interconnected blocks of suitable forest habitat, primarily through the creation and effective management of protected areas. Deforestation needs to be halted, particularly within the ranges of threatened tenrecs (Fig. 1). Habitat restoration will be needed in some sites affected by mining or logging. If protection and restoration measures also incorporate riverine forest corridors, enhance connectivity between forest blocks and conserve areas with high levels of altitudinal variation, they will help maximize species' capacity to respond to a changing climate (Hannah et al., 2008). Climate models that overlay the distribution of threatened tenrecs with protected areas and remaining habitat are needed to identify priority areas for protection and restoration efforts in Madagascar.

The most important habitat types for tenrecs are dry forest, moist lowland forest, moist montane forest and dry shrubland, as well as permanent rivers, streams and creeks (Table 2). The inclusion of a representative sample of these habitats in the protected area network, especially in tenrec range, needs to be verified. There are 15 protected areas currently known to be important for threatened taxa (Table 3) and these sites should be prioritized for conservation action. Government agencies, protected area managers, NGOs, local communities and the private sector will need to work together to improve the integrity and management effectiveness within protected areas. Priorities, as identified by Gardner et al. (2018), include enhancing stakeholder participation, improving law enforcement and reducing the natural resource dependence of local communities through the development of alternative livelihoods.

The livelihood needs of local people need to be addressed if conservation efforts are to succeed (Waeber et al., 2016). Developing alternatives to forest resources such as timber, fuelwood and wild meat would reduce the impact on natural forests. Community forest management schemes, especially those excluding commercial logging (Rasolofson et al., 2015), and broader forest restoration programmes have demonstrated some promising results in improving resource access and livelihoods in Madagascar (e.g. Mansourian et al., 2016). Rural demand for wild meat can be reduced through price increases driven by law enforcement efforts to reduce supply (see Golden et al., 2014). The protection efforts to reduce supply should be complemented with efforts to reduce demand, for example by increasing the supply of meat from domesticated animals, such as poultry (Apaza et al., 2002; Golden et al., 2014), as long as this supply is environmentally sustainable.

Multi-taxonomic approaches to prioritization can enhance biodiversity conservation (Kremen et al., 2008). Given tenrec habitats are also home to higher profile species such as lemurs, for which more concerted conservation efforts are being made (Reuter & Venart, 2014; Schwitzer et al., 2014), it would be prudent to integrate tenrecs into conservation projects targeting other threatened species by, for example, promoting protection of areas critical for threatened tenrecs and including tenrecs in education and awareness campaigns. Five of the 15 protected areas conserving threatened tenrecs are also priorities for lemur conservation (Schwitzer et al., 2014): Anjanaharibe-Sud Special Reserve, Ankeniheny-Zahamena Corridor, Makira Natural Reserve, Marojejy National Park and Ranomafana National Park. The national and international NGOs and research institutes that work in and around these five protected areas (including Association Mitsinjo, Centre ValBio, Conservation International, Duke Lemur Center, Lemur Conservation Foundation, The Aspinall Foundation, the Wildlife Conservation Society and WWF), as well as those operating in other sites, should ensure tenrec diversity is

considered in their monitoring and conservation programmes (see Table 3).

Efforts to conserve and sustainably manage forests important for tenrecs and other species need to increase their investments in capacity building (Waeber et al., 2016). Priorities should include supporting local communities engaged in resource management and staff from agencies managing protected areas, such as Madagascar National Parks and the Direction de Système des Aires Protégées in the Ministry of Environment, Ecology, Seas and Forests. Approaches also need to be diversified. For example, local village governance bodies, such as *dina*, which oversee the application of traditional community regulations, could be supported in improving the internal control of habitat exploitation and hunting, in some instances by reinforcing local taboos on tenrecs.

In protected areas harbouring threatened tenrecs (Table 3), the monitoring of key species population trends needs to be integrated into site management. This will require training and capacity building and the development of standardized monitoring protocols adapted to local needs and habitats, using modern techniques such as camera trapping and specialized techniques for fossorial, arboreal and aquatic species that are difficult to trap. Most of the tools and skills are already present in-country, but need to be scaled up. To improve adaptive management, additional monitoring is required to track changes in forest cover, fragmentation and intactness (using data from satellite-based remote sensing and aerial surveys). In parallel, threats and illegal activities need to be tracked, for example with the Spatial Monitoring and Reporting Tool (SMART, 2018), which has been adopted nationally but is not yet used in all protected areas. Madagascar National Parks, the national agency responsible for managing c. 50% of the island's protected areas, already uses the Management Effectiveness Tracking Tool (WWF, 2007). This tool applies a score card approach to measure a range of variables important for effective management, from legal status and planning to budgets and equipment. It could be introduced to new sites, together with a peer-review process to enhance consistency in application.

Priorities for advancing knowledge on tenrecs

To improve the data available for IUCN Red List assessments and conservation planning, knowledge gaps in tenrec biology, ecology, taxonomy and distribution need to be filled. All research programmes should incorporate opportunities for building capacity among Malagasy students, scientists and academic institutions to ensure the sustainability of research and monitoring work. Small mammal ecology and conservation should also be integrated into the curricula of national universities. Citizen science

¹Alliance for Zero Extinction (AZE) sites contain 95% or more of the remaining population of one or more tenrec species listed as Endangered or Critically Endangered (sensu Ricketts et al., 2005).

²Priority lemur site details from Schwitzer et al. (2013, 2014).

³Lemur species are listed only for priority lemur sites.

research projects conducted in collaboration with local people could help access traditional knowledge and improve our understanding of tenrec distribution, habitats and threats (especially for larger species).

Priority areas for research include investigating: (1) The ecology, distribution and abundance of the four-toed mole tenrec, using appropriate pitfall trapping techniques to survey areas close to its known range (e.g. in and around Andringitra National Park). (2) The distribution of the aquatic tenrec, using live trapping or camera trapping and/or scat surveys. Success would be enhanced by engaging the help of protected area managers and fishing communities. (3) The range of the highland streaked tenrec, to verify whether it is threatened under B criteria. (4) The extent to which tenrec species diversity and abundance are affected by forest structure, habitat degradation, fishing bycatch, hunting and climate change. (5) Methods and protocols required for monitoring tenrecs, including the compilation of suitable guidelines and tools (e.g. identification guides, manuals describing trapping methods, collecting DNA samples, etc.). (6) Habitat cover trends and land use changes, using open-source satellite-based remote sensing data.

The study of Tenrecidae systematics, including taxonomy, needs to be continued to identify cryptic species and clarify species limits and diversity. Two newly delineated but unnamed species of *Oryzorictes* need to be described, which will involve confirming the identities of several holotypes (Everson et al., 2018). The likely presence of a cryptic species in the genus *Geogale* also requires investigation (Poux et al., 2008; Everson et al., 2016).

Research data need to be made available to decision makers in governmental and non-governmental agencies to inform and influence policy, especially relating to protected area management and the control of hunting and mining. The presence of long-term research teams in protected areas may also help deter illegal hunting and logging (Schwitzer et al., 2014).

Conclusions

Small mammals are often given less scientific and conservation attention than larger species even though they are just as threatened (Entwistle & Stephenson, 2000; Stephenson, 2017). In Madagascar, native small mammals are notably diverse and entirely endemic to this island, so it is vital to address the threats facing this neglected group. The largest threat facing tenrecs, habitat loss, reflects a global trend for small mammals whose conservation status is mostly determined by range size and number of locations (Schipper et al., 2008; Kennerley et al., 2018). The only previous assessment of tenrec conservation needs (Nicoll & Rathbun, 1990) highlighted many of the same priorities presented here around habitat conservation and improving our knowledge

of species distribution and status. Although our knowledge of tenrecs has advanced considerably since 1990, no conservation projects have targeted the Tenrecidae explicitly. Therefore, in the next 10 years, there needs to be a strategic effort to integrate the forest habitats of key threatened endemic species such as tenrecs into broader conservation and sustainable development programmes, and to increase the scientific study and monitoring of tenrecs and other mammals. The conservation priorities we have identified need to be translated into fundable projects, following consultative planning processes (e.g. Conservation Measures Partnership, 2013) that involve key stakeholders, such as government agencies, civil society bodies, local communities, business and industry, and donors. The existence of numerous conservation projects across Madagascar, and the continued interest of international donors and NGOs, suggests that implementing tenrec projects will be economically and practically feasible, especially if linked to higher profile taxa. Ultimately, however, only a more concerted effort by the government of Madagascar and its civil society partners and donors to conserve and sustainably manage the country's remaining forests will ensure the continued survival of endemic tenrec species.

Acknowledgements We thank Natalia Ocampo (ETH Zürich) for compiling Fig. 1.

Author contributions IUCN Red List assessments in 2015–2016: PJS, VS and SMG; data contribution: MEN, VA, KME, MH, PDJ, LEO, MR, FR, DR, VR and NR; review of assessments: AT; first draft: PJS, with subsequent input from all co-authors. PJS, VS, SMG, MEN, KME, MH, PDJ, LEO, MR and AT are current members of the IUCN SSC Afrotheria Specialist Group.

Conflicts of interest None.
