

PP414 Improving The Accessibility Of Scottish Medicines Consortium Advice

Miranda Pierre (Miranda.pierre@nhs.scot),
Jackie McCormack, Jennifer Dickson,
Lindsay Lockhart and Noreen Downes

Introduction. The Scottish Medicines Consortium (SMC) provides advice on which new medicines should be accepted for routine use by the NHS in Scotland. To help increase the accessibility of the advice, SMC produces public information summaries, which have been published on the SMC website since 2018. We conducted an evaluation to investigate if the public summaries are achieving their purpose and subsequently help inform improvements from a user perspective. The objectives were to determine how the public summaries are being used; what users like and what could be improved; and if they have achieved a greater understanding of decisions.

Methods. The first stage of the evaluation involved surveying patient groups (organizations that represent the interests of patients, families and carers) to investigate how they use the public summaries. We then conducted workshops with patient groups and Public Partners (members of the public that volunteer with Healthcare Improvement Scotland) to gather perspectives on the content, language and layout of a selection of public summaries.

Results. The survey responses (n = 14) illustrate that the public summaries are being used in a variety of ways. The majority (n = 10) of patient groups reported using the public summaries to help explain SMC decisions to the people they support.

The workshops highlighted that participants found the public summaries clear and helpful. In general, patient groups felt the level of detail and language used in the public summaries improved their understanding of SMC decisions compared to other sources of information, such as the press release or Detailed Advice Document.

There were a number of suggested improvements, including changing the layout (so the SMC decision appears first) and providing definitions for some technical terms. Where actionable, these recommendations have been implemented.

Conclusions. Working in partnership with patient groups and Public Partners has enabled SMC to further strengthen public summaries, and patient engagement more broadly. Improvements have ensured that SMC's decisions are communicated clearly, helping to increase accessibility.

PP424 Piloting A Comprehensive Search For eHealth Definitions In The Grey Literature: Preliminary Results From A Systematic Scoping Review

Zsombor Zrubka (zrubka.zsombor@uni-obuda.hu),
Anita Burrell, Menna N Sharkawy, Colin M Pfeiffer,
Manthan D Janodia, Mete Saylan, Cecile van Steen,
Hossein Motahari-Nezhad and Ken Redekop

Introduction. The use of information technology within health systems has emerged over the years and the current pandemic has further catalyzed this development. As a result, various definitions of eHealth have emerged. Our objective was to provide an overview of definitions available on the internet to complement the traditional (“white”) literature search.

Methods. We adapted methodological guidelines from the Cochrane Handbook and management sciences to mirror the search in bibliographic databases. A comprehensive Google search was performed in July 2020 to retrieve uniform resource locators (URL's) of webpages containing terms for eHealth within four words of synonyms for the word “definition”. The DataScraper extension of the Google Chrome browser was used to collect all URL's. Webpages were eligible if they contained an original or adopted English-language definition of eHealth or contained a direct link to a definition or a document containing a definition. All document types were eligible. The analysis was performed 7 months after the data collection.

Results. Out of the 270 unique URL's, 37 (13.7%) were no longer accessible and 51 (18.9%) were links to academic publications (“white” literature). The language was not English for five webpages (1.9%) and 113 (41.9%) did not contain a definition of eHealth or other related terms. Other related terms were defined in 29 webpages (10.7%), among which “electronic health record” occurred most frequently (18/29, 62.1%). eHealth was defined in 35 (13.0%) webpages, out of which 45.7 percent (16/35) cited an existing source and 54.3 percent (19/35) provided an original definition.

Conclusions. The digital era raises both challenges and opportunities in conducting a grey literature search. We found that an augmented Google-based search can identify valuable references that traditional literature searches cannot detect. Term definitions (and their context) found in the grey versus bibliographic databases will be compared to assess their alignment with health economists perspectives.

PP428 Rechargeable Versus Recharge-Free Sacral Neurostimulation: An Australian Health Economics Analysis

Rashmi Joglekar (rashmi.joglekar@medtronic.com)
and Alexandra Cordato

Introduction. Sacral neuromodulation is a well-established therapy for urinary and fecal incontinence. Currently available sacral neurostimulators require replacement every three to five years due to battery depletion. New rechargeable sacral neurostimulators with a potential 15-year battery life now have regulatory approval in Australia. However, the initial outlay for the device is higher than for the predicate devices. Our objective was to assess the economic value of rechargeable devices, compared with recharge-free implants, and to identify the patients most likely to benefit from the introduction of this novel technology in Australia.

Methods. The Medicare database was reviewed to quantify populations likely to derive benefits from rechargeable technology. Cost minimization and budget impact analyses were conducted from a payer perspective. Cost inputs were derived from Medicare and

the Private Hospital Data Bureau. Two scenarios were modeled comparing the three and five-year battery life of the recharge-free devices with 15 years for a rechargeable device. Sensitivity testing was conducted based on potential uptake and dropout rates (due to death, dementia, etc.).

Results. Rechargeable neurostimulators were found to be dominant (cost-saving) in all modeled scenarios, facilitated by a reduction in the frequency of battery replacement procedures and their associated risks for patients. Rechargeability also facilitated higher power settings for optimal symptom control, without trading off device longevity. Younger patients are expected to derive the greatest benefit from the extended battery life as data showed that 40 percent of the implantations were for patients younger than 65 years. The key uncertainty in this analysis was the limited real-world data on patient selection and preferences, which may influence uptake and dropout rates.

Conclusions. Rechargeable sacral neurostimulators deliver cost savings to the healthcare system due to their extended battery life. Fewer replacement surgeries are an important patient-relevant outcome, especially for younger populations. This finding is important because it demonstrates the economic value of rechargeability to payers and provides robust evidence supporting therapy access for privately insured patients in Australia.

PP439 Data Driven Subgroups Of Patients With Type 1 Diabetes Based On Health Technology For Insulin Delivery

Francisco Javier Somolinos Simón (javier.ssimon@upm.es), Gema García Sáez, Jose Tapia Galisteo and Maria Elena Hernando Pérez

Introduction. Patients with type 1 diabetes (T1D) require the administration of insulin to maintain glycemic control. Currently, two modes of subcutaneous insulin delivery have gained wider acceptance: multiple daily injections (MDI) and continuous subcutaneous insulin infusion (CSII). Randomized controlled trials have shown that CSII is associated with a slightly lower glycated hemoglobin (HbA1c) level when compared with MDI.

The case study on diabetes by the H2020 Next Generation Health Technology Assessment project aims to link evidence from randomized controlled trials to real-world data to estimate the impact of health technology on specific subgroups of patients, as a first step in building prediction models to personalize treatment strategies. This work aims to assess whether patients with T1D can be stratified according to the use of health technology for insulin delivery and associated glycemic control from real-world data.

Methods. We used a longitudinal prospective data repository of T1D patients from 83 clinics in the United States (T1D exchange). A data-driven two-step clustering analysis was done on adult individuals ($n = 8,034$) with more than five years of disease duration. Clusters were based on body mass index (BMI), sex, age at diagnosis, diabetes duration, HbA1c level, and insulin delivery method. The optimal number of clusters was estimated based

on silhouette width.

Results. We identified the following four clusters of T1D patients characterized by differences in gender and insulin delivery method: men and women with insulin injections or pens and men and women with CSII. Individuals that used CSII had lower HbA1c levels, a higher BMI, and longer diabetes duration than those using injections or pens.

Conclusions. This preliminary work identified subgroups of T1D patients linked to insulin delivery methods. Future research includes the study of complications associated with different clusters and additional data sources. While the data were sourced from the T1D Exchange, the analyses, content, and conclusions presented have not been reviewed or approved by the T1D Exchange.

PP447 Informing The Development And Evaluation Of An Evidence-Based Service Delivery Model For Mental Health Patients With Complex Needs

Pooja Saini, Antony Martin (antony@qcmedica.com), Jason C. McIntyre, Laura Sambrook, Hana Roks, Sam Burton, Anna Balmer, Amrith Shetty and Rajan Nathan

Introduction. Mental health services for adults have been developed to provide community-based interventions. There is a recognized unmet need in some of the most complex patients that may not be adequately met by existing mental health services provision. Research is warranted to consider the best model of service delivery for this group of service users. The aims of this research were to examine the profile and history of service users defined as having complex needs as well as their service use and associated costs in the Cheshire and Wirral Partnership NHS Foundation Trust (CWP).

Methods. A diverse group of stakeholders were invited to provide feedback on the content and design of the proforma for data collection from the medical records of service users. The rationale of the data collection was described to ensure relevant patient-level cost information was collected to identify and quantify the relevant resources consumed, to inform the evaluation of direct medical costs, direct non-medical costs, and indirect costs for each patient. The proforma was designed to also permit comparisons of clinical and service use outcomes for evaluation of patient health and non-health outcomes associated with alternative care pathways.

Results. Stakeholder feedback comprised representatives from the CWP, patients, commissioners, the Local Authority, and housing. Relevant data for extraction from patient medical records were identified and a proforma was developed. The following items were identified for inclusion: baseline demographic data, service user data (family background, contact with the criminal justice system, social history), and clinical data (diagnosis, treatment, hospital visits, and other health service use).

Conclusions. A proforma was developed with diverse stakeholder involvement to inform data collection on the resource use
