In a paper published in this journal, Alon, Kohayakawa, Mauduit, Moreira and Rödl proved that the minimal possible value of the normality measure of an N-element binary sequence satisfies

$$\left(\frac{1}{2} + o(1)\right) \log_2 N \leqslant \min_{E_N \in \{0,1\}^N} \mathcal{N}(E_N) \leqslant 3N^{1/3} (\log N)^{2/3}$$

for sufficiently large N, and conjectured that the lower bound can be improved to some power of N. In this note it is observed that a construction of Levin of a normal number having small discrepancy gives a construction of a binary sequence E_N with $\mathcal{N}(E_N) = O((\log N)^2)$, thus disproving the conjecture above.

AMS 2010 Mathematics subject classification: Primary 68R15 Secondary 11K45, 11K16

Let there be given a finite binary sequence

$$E_N = (e_1, \ldots, e_N) \in \{0, 1\}^N.$$

For $k \ge 1$, $M \ge 1$ and $X \in \{0, 1\}^k$, we set

$$T(E_N, M, X) = \#\{n : 0 \le n < M, \text{ and } (e_{n+1}, \dots, e_{n+k}) = X\},\$$

which means that $T(E_N, M, X)$ counts the number of occurrences of the pattern X among the first M + k - 1 elements of E_N . The normality measure $\mathcal{N}(E_N)$ is defined by

$$\mathcal{N}(E_N) = \max_{1 \le k \le \log_2 N} \max_{X \le \{0,1\}^k} \max_{1 \le M \le N+1-k} \left| T(E_N, M, X) - \frac{M}{2^k} \right|. \tag{1}$$

The normality measure was introduced in 1997 by Mauduit and Sárközy [8], together with several other measures of pseudorandomness for finite binary sequences. In two papers, Alon, Kohayakawa, Mauduit, Moreira and Rödl [2, 3] (hereafter AKMMR) studied the *minimal* and *typical* values of the normality measure (and other measures of pseudorandomness). Concerning the typical value of \mathcal{N} , they proved that for any $\varepsilon > 0$ there exist $\delta_1, \delta_2 > 0$ such that, for E_N uniformly distributed in $\{0,1\}^N$,

$$\delta_1 \sqrt{N} \leqslant \mathcal{N}(E_N) \leqslant \delta_2 \sqrt{N}$$

holds with probability at least $1 - \varepsilon$ for sufficiently large N, and conjectured that a limit distribution of $\mathcal{N}(E_N)/\sqrt{N}$ exists; the latter was recently confirmed [1]. Concerning the minimal value of \mathcal{N} , AKMMR proved that

$$\left(\frac{1}{2} + o(1)\right) \log_2 N \leqslant \min_{E_N \in \{0,1\}^N} \mathcal{N}(E_N) \leqslant 3N^{1/3} (\log N)^{2/3}$$
 (2)

for sufficiently large N. The lower bound in (2) is based on a relatively simple combinatorial argument. The proof of the upper bound in (2) is rather elaborate; however, it is entirely constructive, using an explicit algebraic construction based on finite fields. Concerning a possible improvement of (2), AKMMR write in [2] that

'We suspect that the logarithmic lower bound in [equation (2)] is far from the truth.' and formulate the open problem

Is there an absolute constant $\alpha > 0$ for which we have $\min_{E_N} \mathcal{N}(E_N) > N^{\alpha}$ for all large enough N? In [3] they write

'The authors believe that the answer to [the open problem above] is positive.'

The purpose of this note is to draw attention to a result of Levin [7] concerning the existence of a normal number with small discrepancy. This result implies the following upper bound on the minimal value of \mathcal{N} , closing the gap between upper and lower bounds up to a logarithmic factor, and disproving the conjecture of AKMMR stated above.

Theorem 1. There exists a constant c such that

$$\min_{E_N \in \{0,1\}^N} \mathcal{N}(E_N) \leqslant c (\log N)^2$$

for sufficiently large N.

Normal numbers were introduced by Borel in 1909. Let $z \in [0,1)$ be a real number, and denote its binary expansion by $z = 0.z_1z_2z_3...$ Then z is called a *normal number* (in base 2, which is the only base that interests us in the present paper) if, for any $k \ge 1$ and any block of digits $X \in \{0,1\}^k$, the relative asymptotic frequency of the number of appearances of X in the binary expansion of z is 2^{-k} . Using the terminology from the

¹ Strictly speaking, Mauduit and Sárközy defined their pseudorandomness measures for sequences over the alphabet {-1,1} (instead of {0,1}, as in the present paper). It is more convenient for our purposes to study sequences defined over the alphabet {0,1} (since they can be related to the binary representation of real numbers), and the definitions have been modified accordingly.

344 C. Aistleitner

beginning of this note and writing $Z_N = (z_1, \dots, z_N)$ for the sequence of the first N digits of z, this can be expressed as

$$\lim_{N \to \infty} \frac{T(Z_N, N+1-k, X)}{N} = 2^{-k},$$

where k is the length of X. Borel proved that almost all numbers (in the sense of the Lebesgue measure) are normal. There exist many constructions of normal numbers, the first obtained by concatenating the digital representations of the positive integers (Champernowne, 1933), primes (Copeland and Erdős, 1946) and values of polynomials (Davenport and Erdős, 1952). It is a very difficult problem to decide whether a given real number is normal, and it is unknown whether constants such as $\sqrt{2}$, e and π are normal.

In an informal way, normal numbers are often considered to be numbers showing 'random' behaviour (which is justified by the above-mentioned theorem of Borel). In fact, different variants of the normality property were considered as tests for pseudorandomness of (infinite) sequences of digits, for example in Knuth's monograph *The Art of Computer Programming* [5], and the normality measure of Mauduit and Sárközy is a quantitative version of such a pseudorandomness test for the case of a *finite* sequence of digits. For a discussion of the connection between normal numbers, pseudorandomness of (finite) sequences, and pseudorandom number generators, see Knuth's book [5] and Mauduit and Sárközy's papers 'On finite pseudorandom binary sequences I–VII' (*e.g.*, [8]), as well as Bailey and Crandall [4] and Niederreiter [9].

To proceed further, we need some notation. A sequence of real numbers $(y_n)_{n\geqslant 1}$ from the unit interval is called *uniformly distributed modulo one* (u.d. mod 1) if, for all intervals $[a,b) \subset [0,1)$, we obtain the limit relation

$$\lim_{N \to \infty} \frac{1}{N} \sum_{n=1}^{N} \mathbb{1}_{[a,b)}(y_n) = b - a.$$

The quality of the uniform distribution of a sequence is measured in terms of the discrepancy D_N , which for $N \ge 1$ is defined by

$$D_N(y_1, \dots, y_N) = \sup_{0 \le a < b \le 1} \left| \frac{1}{N} \sum_{n=1}^N \mathbb{1}_{[a,b)}(y_n) - (b-a) \right|.$$

A sequence is u.d. mod 1 if and only if its discrepancy tends to zero as $N \to \infty$.

By an observation of Wall [11], a number z is normal (in base 2) if and only if the sequence $(\langle 2^{n-1}z\rangle)_{n\geqslant 1}$, where $\langle \cdot \rangle$ denotes the fractional part, is u.d. mod 1. Korobov [6] posed the problem of finding a function $\psi(N)$ with maximal decay for which there exists a number z such that

$$D_N(z, \langle 2z \rangle, \dots, \langle 2^{N-1}z \rangle) \leqslant \psi(N), \quad N \geqslant 1.$$

The best current result concerning this question is due to Levin [7], who proved (constructively, by giving an explicit example) the existence of a z for which

$$D_N(z, \langle 2z \rangle, \dots, \langle 2^{N-1}z \rangle) = O\left(\frac{(\log N)^2}{N}\right) \text{ as } N \to \infty.$$
 (3)

This result should be compared with a lower bound of Schmidt [10], stating that for any sequence $(y_n)_{n \ge 1}$,

$$D_N(y_1,\ldots,y_N) \geqslant c_{\text{abs}} \frac{\log N}{N}$$

for infinitely many N. Thus Korobov's problem is solved, up to a logarithmic factor. In view of Levin's result (3), Theorem 1 is a direct consequence of the following lemma.

Lemma 2. Let $z \in [0,1)$ be a real number whose binary expansion is given by $z = 0.z_1z_2z_3$, ..., and assume that there exists a non-decreasing function $\Phi(N)$ such that

$$D_N(z,\langle 2z\rangle,\ldots,\langle 2^{N-1}z\rangle) \leqslant \frac{\Phi(N)}{N}, \quad N\geqslant 1.$$
 (4)

Then, for each $N \geqslant 1$ the binary sequence $Z_N = (z_1, ..., z_N)$ satisfies

$$\mathcal{N}(Z_N) \leqslant \Phi(N)$$
.

Proof. We may suppose that z is not a dyadic rational. For any k, any binary sequence X of length k, and any $M \le N+1-k$, it is immediately seen that $T(Z_N, M, X)$ is the number of indices $0 \le n \le M-1$ for which $\langle 2^n z \rangle$ falls in a certain interval of length 2^{-k} . Hence

$$\left|T(Z_N, M, X) - \frac{M}{2^k}\right| \leqslant MD_M(z, \langle 2z \rangle, \dots, \langle 2^{M-1}z \rangle) \leqslant \Phi(M) \leqslant \Phi(N),$$

so $\mathcal{N}(Z_N) \leqslant \Phi(N)$, as claimed. By the remark before the statement of the lemma, this also proves Theorem 1.
