

Taxonomy of the genus *Myrionora*, with a second species from South America

Zdeněk PALICE, Christian PRINTZEN, Toby SPRIBILLE, Måns SVENSSON, Tor TØNSBERG, Irina URBANAVICHENE, Lidia S. YAKOVCHENKO and Stefan EKMAN

Abstract: A taxonomic and biogeographic overview of the genus *Myrionora* is provided. Two species are recognized, *M. albidula* (Willey) R. C. Harris and *M. pseudocyphellariae* (Etayo) S. Ekman & Palice comb. nov. The genus is characterized by polysporous asci, the presence of crystals in the hymenium and proper exciple that partly consist of lobaric acid, and a photobiont with large cells (mostly in the range 12–20 µm). *Myrionora albidula* is currently known from Germany, Norway, Sweden, the Russian Federation (Altayskiy Krai, Chelyabinskaya Oblast', Khabarovskiy Krai and Zabaykal'skiy Krai), and the United States (Alaska, Connecticut, Maine and Massachusetts). It inhabits bark of deciduous trees and shrubs and conifers over a wide range of latitudes. *Myrionora pseudocyphellariae* is known from Chile and Ecuador, where it has been encountered on lichens and decaying bark. Based on morphological characteristics, we conclude that *Myrionora* belongs in the *Ramalinaceae*.

Key words: *Bacidia*, *Jarmania*, lichens, polysporous asci, *Ramalinaceae*, *Scoliciosporum*, taxonomy

Introduction

The genus *Myrionora* was described to accommodate a single species, *M. albidula*, that was at the same time reported from Maine (Harris in Harris *et al.* 1988). The name was based on *Biatora albidula*, a minute and poorly known species that had previously been collected near New Bedford, Massachusetts, in 1884 (Willey in Tuckerman 1888). On account of its polysporous asci, it was treated as *Biatorella albidula* by Zahlbruckner (1928) and Magnusson (1935). Ekman (1996) retained *Myrionora* but speculated that it might be related to *Scoliciosporum*, as polyspory was already known in *S. curvatum* Sérus. The combination *Scoliciosporum albidulum* was eventually made by Etayo (in Etayo & Sancho 2008). The fact remained, however, that Willey's type material had not been scrutinized since Magnusson's work on *Biatorella* in the 1930s.

In recent years, all of the authors independently discovered what later turned out to be *M. albidula* in very different parts of

the world. Spribille *et al.* (2010) reported the species from Alaska, along with a brief mention of finds from Europe and Russia. A subsequent review of all material that has been brought to our attention, including Willey's type material, has provided a picture of the morphology, chemistry and relationships of *M. albidula* that substantially augments the little information currently available in the literature. Suspicion also arose that the recently described *Scoliciosporum pseudocypbellariae* Etayo (Etayo & Sancho 2008) might represent a close relative of *M. albidula*, an idea that turned out to be correct upon closer examination. In the light of the extended number of available specimens of *M. albidula* and the discovery of a second species, we aim to summarize current knowledge of the members of *Myrionora* and to discuss generic affinities.

Materials and Methods

Paraphyses, ascospores, and excipular hyphae were consistently measured in 10% aqueous KOH, because they were otherwise obscured by crystals. The width of the excipular rim surrounding the apothecial disc was measured in sections, following Ekman (1996: 55). Ascus apex structures were observed in an aqueous solution of 0.3% I₂ and 0.6% KI, following pretreatment with KOH to remove crystals and separate paraphyses. Quantitative characters for which data was collected systematically were checked for deviations from normality using EasyFit Professional 5.0. Methods for thin-layer chromatography followed Arup *et al.* (1993). Measurements of apothecia, hymenium, paraphyses, and ascospores are given as 'minimum – first quartile – median – third quartile – maximum' together with the total sample size *n*. Abbreviations of herbaria follow *Index Herbariorum* (<http://sciweb.nybg.org/science2/IndexHerbariorum.asp>), except KLGO, which refers to the Klondike Gold Rush National Historical Park herbarium in Skagway, Alaska.

Taxonomy

Myrionora R. C. Harris

in Harris *et al.*, *Evansia* 5: 27 (1988); type: *M. albidula* (Willey in Tuck.) R. C. Harris (generic type species).

Thallus crustose. *Photobiont* chlorococcoid, cells globose or ellipsoid, unevenly sized, (7–)12–20(–24) µm long with a median *c.* 16 µm.

Apothecia biatorine, sometimes more or less speckled with blue-green (K–, N+ purple-red) pigment in epithecium and/or excipular rim. *Proper exciple* composed of hyphae with heavily gelatinized cell walls, not separating when squashed in K, interspersed with abundant, minute, colourless, bacilli-form crystals up to 1(–2) µm long, most of which are soluble in K and insoluble in N and acetone. *Excipular hyphae* irregularly dichotomously branched as well as anastomosing, not clearly radiating towards edge, cell lumina up to 2.5 µm wide, unevenly thick and constricted at septa, terminal cells not or moderately enlarged (to 4 µm wide), sometimes with blue-green pigment around terminal cells. *Hypothecium* colourless, composed of irregularly branched and thin-walled cells with cell lumina up to 4 µm wide. *Hymenium* poorly delimited from tissues below, in upper part with same crystals as in exciple, colourless except for occasional blue-green pigment crystals encrusting terminal paraphysis cells or embedded in hymenial gel further down in hymenium. *Paraphyses* superficially similar to excipular hyphae, more or less dichotomously branched and occasionally anastomosing, abundantly branched in uppermost part, apices not or moderately enlarged, partially almost parallel to apothecial surface, often forming a network of hyphae above the asci. *Asci* clavate, outermost wall layer slightly thicker around apex compared to rest of ascus; young spore mass with a pointed ocular chamber; tholus staining dark blue in I with a paler blue, narrowly conical axial body and a deep blue zone surrounding the axial body (= '*Biatora*-type' *sensu* Hafellner 1984). *Ascospores* more than 12 per ascus, non-septate, more or less ellipsoid, short-bacilliform with rounded ends, or broadly ovoid.

Chemistry. Both species probably contain lobaric acid as part of the hymenial crystal layer, as evidenced by the C– but KC+ transiently purple reactions in apothecial sections. Although difficult to see because of the small size of the apothecia, the reaction with KC was consistent when observed on a microscope slide against a white background

through a stereo microscope. The KC reaction is identical to the one seen in apothecia of *Scoliciosporum pruinosum*, in which the presence of lobaric acid has been confirmed (Tønsberg 1997). We did not attempt chromatographic identification of substances in the lectotype of *M. albidula*, nor in any of the specimens of *M. pseudocyphellariae*. We did, however, perform HPTLC on apothecial tissue from two other specimens of *M. albidula* (Palice 11222 and Printzen 8544), which turned out negative, possibly because of the small amounts of lobaric acid in the crystal layer. It should also be noted that the majority of the crystal layer consists of one or more other substances, as most crystals are insoluble in acetone.

Notes. The generic description above is essentially an account of the characteristics that the two species currently included have in common. Should the circumscription of *Myrionora* (see Discussion below) change to include an ensemble of species currently treated in *Jarmania*, *Scoliciosporum* and *Bacidia*, the generic characteristics will of necessity change.

According to our observations, young and undamaged asci in *Myrionora* always possess the *Biatora*-type apex structure. However, *Lecanora*-type asci have been reported for both species (see references under the species below). We have noticed that asci in *Myrionora* are extremely fragile, particularly after pretreatment with KOH, and easily rupture basally if the preparation is squashed more than very lightly. Such damaged asci often display a *Lecanora*-type apex structure. As already pointed out by Hafellner (1984: 250), ruptured asci often display quite different apex structures than undamaged ones.

Distributions of quantitative characters in *Myrionora* were generally right-skewed, the best-fitting ones often being Wakeby or Burr distributions. Kolmogorov-Smirnov tests of goodness of fit rejected normality at $P \leq 0.05$ for ascospore width and length-breadth ratio in *M. albidula*, and apothecial size in both species. This prompted us to select medians and quartiles instead of means and standard deviations to describe quantitative variation in the species below.

Key

- 1 Apothecia pale yellowish with blue speckles to bluish black; ascospores ≥ 32 per ascus, more than twice as long as wide; hymenium always ≥ 35 μm and usually ≥ 40 μm thick **M. albidula**
 Apothecia yellowish white; ascospores ≤ 24 per ascus, less than twice as long as wide; hymenium ≤ 35 μm thick **M. pseudocyphellariae**

M. albidula (Willey in Tuck.) R. C. Harris

in Harris et al., *Evansia* 5: 27 (1988).—*Biatora albidula* Willey in Tuck., *Syn. N. Am. Lich.* 2: 130 (1888).—*Biatorella albidula* (Willey) Zahlbr., *Cat. Lich. Univ.* 5: 34 (1928).—*Scoliciosporum albidulum* (Willey) Etayo in Etayo & Sancho, *Bibl. Lichenol.* 98: 223 (2008); type: USA, Massachusetts, Bristol Co., “on beech, N. B.” (=New Bedford), 1884, H. Willey (FH-TUCK barcode 302680 sheet 2883, lectotype selected here; FH-TUCK barcode 302682 sheet 2884, isotype, both seen).

(Figs 1A, 2A–D)

Thallus crustose, endophloeodal to thinly epiphloeodal, when epiphloeodal consisting of minute granules on which apothecia form, whitish to pale grey, without prothallus.

Apothecia 0.11–0.18–0.21–0.27–0.50 mm diam. ($n = 120$), at first flat, becoming convex with age, starting as sessile on thallus, often becoming constricted at base. *Disc* whitish to dark blue-grey, often piebald with bluish speckles, occasionally entirely whitish or yellowish. *Margin* level with disc, at first distinct but becoming partially excluded with

FIG. 1. *Myrionora*, thalli with apothecia. A, *M. albidula* (Harris 46105); B, *M. pseudocyphellariae* (Etayo 23245, Gómez-Bolea, Sechting & Vilches). Scales = 0.5 mm. In colour online.

age, usually paler than disc (occasionally concolorous). *Proper exciple* forming 35–60 μm wide rim around disc, unpigmented except sometimes with more or less abundant blue-green pigmentation around terminal cells. *Hymenium* 35–45–55–60–65 μm thick ($n = 15$). Paraphyses \pm abundant, dichotomously branched in upper half and occasionally anastomosing, 1.2–1.7–1.9–2.1–2.7 μm wide in mid-hymenium ($n = 120$); apices not or moderately swollen, 1.6–2.2–2.6–3.0–5.0 μm wide ($n = 56$), occasionally coated with blue-green pigment that extends as coarse crystals deep into the hymenium. *Ascospores* more than 32 per ascus (“50–75” according to Magnusson 1935, “>30” according to Sérusiaux 1993), narrowly ellipsoid to short-bacilliform with rounded ends, 4.7–6.0–6.6–7.6–11.3 μm long, 1.6–2.0–2.2–2.3–3.3 μm wide, 2.2–2.7–3.0–3.6–5.1 times as long as wide ($n = 120$).

Pycnidia seen in a single specimen (*Urbana-vichene* L10352), unilocular, of two types: 1) semi-immersed to immersed, globose, 25–30 μm wide, with protruding masses of conidia. *Conidia* broadly ellipsoid 2.5–3.5 \times 1.5–2.0 μm ; 2) immersed, semiglobose but slightly flattened and resembling juvenile apothecia, 40–60 μm wide. *Conidia* ellipsoid, 3.0–4.0(–4.5) \times 1.3–1.7 μm . Wall of both pycnidial types with the same blue-green pigment as in the apothecia. Conidiogenous

cells lining wall of pycnidial cavity, narrowly cylindrical, forming conidia acrogenously.

Distribution and habitat. *Myrionora albidula* appears to be a circumpolar species occupying the deciduous and coniferous forest belts in the northern temperate zone (Fig. 3). Its altitudinal range stretches from near sea level to around 1400 m above sea level in southern Transbaikalia, and its latitudinal distribution spans from around 41°N in New England to over 63°N in Norway. Habitats include deciduous, coniferous, or mixed forests, where the species inhabits smooth or moderately rough bark of *Alnus*, *Sorbus*, *Salix*, *Fagus*, *Acer*, *Quercus*, *Picea*, and *Abies* in shade or semi-shade. In one of the localities in Russian Transbaikalia, the substratum choice is extended to dry decorticated twigs of *Abies sibirica*. One of the two Swedish localities deviates from these natural forest habitats by consisting of an overgrown garden at an abandoned farm, where *M. albidula* was found to be abundant on shrubs of planted *Syringa vulgaris*. We believe that *M. albidula* is rare but widespread throughout the northern temperate zone. It has been widely overlooked but may, if given the proper attention, turn out to be locally frequent. The main reason for being overlooked is that it forms very small thalli with minute apothecia, which, even if detected, may be mistaken for juvenile

FIG. 2. *Myrionora*, apothecial anatomy. A–D, *M. albidula*; A, section through apothecium of *M. albidula*, showing crystals blocking the light and causing the impression of brown pigmentation (Harris 46105); B, same as in A but through polarized light, showing shining white crystals; C, asci with ascospores in *M. albidula* (lectotype, 1884 Willey); D, young ascus in *M. albidula* showing apex structures (Palice 11222). E–F, *M. pseudocyphellariae*; E, asci with ascospore (Palice 3710); F, paraphyses (Palice 3710). Scales: A & B = 100 μm ; C–F = 10 μm . Illumination: bright field (A), cross-polarized light (B), differential interference contrast (C–F). Matrix: pure water (A & B), pure water with some 10% aqueous KOH added. In colour online.

FIG. 3. Known world distribution of *Myrionora albidula*.

or stunted apothecia of other crustose lichens with biatorine apothecia.

Comments. The ascus in *M. albidula* has been referred to the “*Lecanora*-type” (Harris *et al.* 1988; Sérusiaux 1993). In our experience, however, the ascus is consistently of *Biatora*-type, which can also be described as a *Bacidia*-type with a dark amyloid zone around the axial body. The characteristic bluish pigment often present in the apothecia was not mentioned by Willey (in Tuckerman 1888) or Magnusson (1935). It was, however, implicated by Harris *et al.* (1988): “. . . the color of the apothecia varies from whitish to dark greenish brown, apparently depending on exposure to light”. In addition, we have observed an inverse relationship between the density and thickness of the apothecial crys-

tal layer and the amount of bluish pigment. Absorption spectra of lobaric acid suggest that this substance provides protection to UV-B radiation (Hidalgo *et al.* 2005).

Additional specimens examined. **Germany:** Baden-Württemberg: Schwarzwald, Kette des Zeller Blauen (Wiesental) beim “Dachseck”, on *Abies*, alt. 1060 m, 47.7347°N 7.8524°E, 31 viii 1913, G. R. Buck* 15330 (NY).

**Myrionora pseudocyphellariae (Etayo)
S. Ekman & Palice comb. nov.**

Mycobank No.: MB 803243

Scoliosporum pseudocyphellariae Etayo in Etayo & Sancho, *Bibl. Lichenol.* 98: 220 (2008); type: Chile, Navarino (35), Lum, bosque costero de lengas, sobre *Pseudocyphellaria vaccina* en *Nothofagus pumilio*, 54°56'25.5''S 68°05'53.5''W, alt. 65 m a.s.l., 26 January 2005, Etayo 23245, Gómez-Bolea, *Söchting* & *Vilches* (MAF—holotype, not seen; hb. Etayo—isotype, seen).

(Figs 1B, 2E–F)

Thallus crustose, episubstratal, composed of minute, granular areoles beneath the apothecia (and much smaller than the apothecia), possibly also consisting of discrete, scattered, minute greenish granules (which cannot be attributed with certainty to this species).

Apothecia 0.07–0.10–0.11–0.13–0.21 mm diam. ($n = 100$), more or less convex from the start, sessile. *Disc* yellowish white. *Margin* indistinct, at first level with disc but soon becoming excluded, concolorous with disc. *Proper exciple* forming c. 30 μm wide rim around disc, unpigmented. *Hymenium* 28–28–31–34–35 μm thick ($n = 6$). *Paraphyses* relatively few, branched mainly in the middle and lower part, 1.6–1.7–1.8–1.9–2.3 μm wide in mid-hymenium ($n = 40$); apices not or very slightly swollen, 1.6–1.8–2.0–2.3–2.7 μm wide ($n = 40$). *Ascospores* 12–24 per ascus, broadly ellipsoid or sometimes broadly ovoid, 3.5–4.0–4.5–4.8–5.2 μm long, 2.4–2.7–2.9–3.4–4.1 μm wide, 1.1–1.3–1.5–1.7–2.0 times as long as wide ($n = 40$).

Pycnidia not seen.

Distribution and habitat. Known from two nearby sites close to sea level in Tierra del Fuego, Chile, and a third locality at high altitude in the Cordillera Real of Ecuador. All localities are ancient woodlands. At the Chilean localities, *M. pseudocyphellariae* was collected on *Pseudocyphellaria vaccina* and *P. coriifolia* on *Nothofagus pumilio*. At the Ecuadorian site, it was found directly on soft decaying bark of *Gynoxys* sp. It was described as a lichenized parasymbiont (hence its epithet), but we have observed a lichenized thallus with a photobiont very similar to the one in *M. albidula*. We suspect that *M. pseudocyphellariae* is simply overgrowing the decaying thalli of *Pseudocyphellaria*. The *Pseudocyphellaria* specimens are also inhabited by other lichens, notably young thalli of *Usnea* and *Parmelia* s. lat.

Comments. The hymenial thickness was given as 40–45 μm in the original description by Etayo & Sancho (2008). Also, these authors depict an ascus of more or less *Lecanora*

type (their fig. 104 on p. 221). However, *M. pseudocyphellariae* possesses a typical *Biatora*-type ascus, with the axial body approaching but not penetrating the strongly amyloid central wall layer of the ascus apex (the d-layer in the sense of Bellemère & Letrouit-Galinou 1988).

Additional specimen examined. Ecuador: Chimborazo: Sangay National Park, El Altar, fragment of *Gynoxys* forest on the crest descending E of Laguna de Collantes ("Yellow Lagoon"), on bark of *Gynoxys*, alt. 4150 m, 1.6694°S 78.4292°W, 1999, *Z. Palice* 3710 (PRA).

Discussion

Myrionora was described by Harris *et al.* (1988) as a member of the *Lecanoraceae*, a view that has been upheld (Hafellner 1995; Lumbsch & Huhndorf 2010). Both species of the genus also have a history of being treated in *Scoliciosporum*, a misunderstanding that was probably caused by 1) the existence of a polysporic member of *Scoliciosporum* s. str., *S. curvatum* Sérus., and 2) the traditional treatment of close relatives of *Myrionora* in *Scoliciosporum*, viz. *S. pruinosum* (P. James) Vězda and allies. However, *Myrionora* is not closely related to *Scoliciosporum* s. str. The latter genus is characterized by having a 'Lecanora-type' ascus apex with a wide axial body that reaches throughout the entire d-layer (in the sense of Bellemère & Letrouit-Galinou 1988), abundantly anastomosed paraphyses, a poorly developed proper exciple, and a lack of crystals in the hymenium. Recent molecular evidence indicates that *Scoliciosporum* s. str. may be the sister group to *Sphaerophoraceae*, *Psoraceae*, and *Ramalinaceae* (Ekman *et al.* 2008). Lumbsch & Huhndorf (2010) treated *Scoliciosporum* in a separate family, the *Scoliciosporaceae*.

The features of *Myrionora* instead place it in the *Ramalinaceae*, more specifically close to *Jarmania* (Kantvilas 1996, 2008) which includes two currently recognized species (the type species *J. tristis* as well as *J. scoliciosporoides*) known from the Australian states of Tasmania and Victoria (Elix *et al.* 2009), as well as the members of the "Bacidia lutescens group" *sensu* Ekman (1996), namely *Bacidia lutescens* Malme, *B. americana* (Fée) Zahlbr., *B. fuscula* (Nyl.) Zahlbr. and *Scoliciosporum*

pruinosum (P. James) Vězda; added to this can be *B. lobarica* Printzen & Tønsberg (Printzen & Tønsberg 2007), *S. schadeanum* (Erichsen) Vězda, and *S. pensylvanicum* R. C. Harris (Harris 2009).

The close relationship between *Jarmania scoliciosporoides* and *Scoliciosporum pruinosum* was first noted by Kantvilas (2008). Apart from the idiosyncratic difference in the number of ascospores per ascus, *Myrionora* shares most features of the apothecial anatomy and chemistry, including the presence of lobaric acid, with most of the above mentioned species. Lobaric acid has previously been reported from a few other members of the *Ramalinaceae*, viz. the two known species of *Myelorrhiza* (Verdon & Elix 1986), *Phyllopsora cinchonarum* (Fée) Timdal (Timdal 2008), as well as *Biatora ligni-mollis* T. Sprib. & Printzen (Spribille *et al.* 2009).

There is reasonable evidence that *J. scoliciosporoides* and the *B. lutescens* groups are congeneric (Ekman 1996; Kantvilas 2008). However, the type species of *Jarmania*, *J. tristis*, is set apart from these species, as well as from *Myrionora*, by the brown hypothecium turning yellowish in K, acicular (not filiform or more or less bacilliform) ascospores, irregular (not minutely bacilliform) crystals in the proper exciple and hymenium, and the presence of grayanic acid instead of lobaric acid. We have observed paraphyses in *J. tristis* (isotype in GZU) that are few, moderately branched and hardly (if at all) anastomosed, which is in contrast to the description given by Kantvilas (1996). Attention should also be given to *Scoliciosporum arachnoideum* (Aptroot 2008), which we have not seen but may turn out to be closely related to *J. tristis*.

If *Myrionora* and *Jarmania* are treated as congeneric, the name *Myrionora* has priority, as it antedates *Jarmania* by eight years. For the time being, however, we think it best to treat *Myrionora* as distinct from *Jarmania*, whether the latter is taken in a strict sense (including only the type species *J. tristis* and possibly also *Scoliciosporum arachnoideum*) or a broad sense (including also *J. scoliciosporoides* and the *B. lutescens* groups) on account of the additional difference in photobiont, the green-

algal cells in *Myrionora* being larger (mostly 12–20 μm) than in *Jarmania* s. lat. (mostly 5–12 μm).

A molecular phylogeny is needed to resolve these relationships. Unfortunately, repeated attempts to acquire DNA sequences from our fresh specimens of *M. albidula* have so far been unsuccessful.

We thank Javier Etayo (Pamplona, Spain) and the curators of the herbaria FH, GZU, and NY for loans of specimens. TS was supported by a grant from the Austrian Science Foundation (FWF P21052-B16). SE was supported by a grant from the Swedish Taxonomy Initiative (dnr. 146/07 1.4). ZP acknowledges financial support for long-term research development (project no. RVO 67985939) and the Ministry of Education, Youth and Sports of the Czech Republic (project no. 0021620828). IU thanks the Ministry of Education and Sciences of the Russian Federation (project no. 16.518.11.7071) and the Russian Foundation for Basic Research (project no. 11-04-00901-a). CP acknowledges a travel grant from the Paul Ungerer Stiftung which made the collecting trip to the Altai Mountains possible.
