Introduction: Internet provides wide opportunities not only for development, but also for developmental risks including information about drug consumption, advocacy for weight loss and suicide (Livingstone et al., 2011).

Objectives: The aim of this study was to compare user activity and online risks in Russian adolescents and parents according to three population studies, 2010, 2013, and 2019.

Methods: Using EU Kids Online methodology (Livingstone et al., 2011), the data of 1219 parents of adolescents 12-17 years old and 1553 adolescents 12-17 years old from 15 regions of Russia in 2019 were compared with the data of 1203 adolescents 12-17 years old and 1209 parents in 2013, as well as the answers of 685 couples "parent - teenager 12-16 years old" in 2010.

Results: Compared to 2010, in 2019 adolescents are more frequently disappointed or worried about something online (41.5% versus 33.6%, $\chi^2=12.44$, $p<.01$, $CC=.07$). Contemporary adolescents rarer report having seen sexual images ($\chi^2=339.48$, $p<.01$, $CC=0.36$) online but more frequently report having seen rude actions online ($\chi^2=69.93$, $p<.01$, $CC=0.16$). They more frequently see information about drugs and suicides ($\chi^2=37.11$, $p<.01$, $CC=0.12$ и $\chi^2=85.04$, $p<.01$, $CC=0.17$, respectively) and report an experience of cyberaggression ($\chi^2=80.85$, $p<.01$, $CC=0.19$) and fraud ($\chi^2=17.75$, $p<.01$, $CC=0.09$).

Conclusions: In Russian sample online risks in adolescents closely related to mental health and risky behavior in 2010-2019 increase suggesting necessity of social programs of risk prevention. Study is supported by Russian science Foundation, project 18-18-00365.

Conflict of interest: Study is supported by Russian science Foundation, project 18-18-00365.

Introduction: Prenatal attachment is a strong predictor of post-natal attachment. Identifying factors influencing this bond is important, especially maternal history of stressful life-events.

Objectives: Determine which type of maternal trauma impacts prenatal attachment.

Methods: We conducted a transversal descriptive study in a first line clinical practice center and in an university gynecology-obstetrics department. We used Prenatal Attachment Inventory (PAI) to assess maternal-fetal attachment, the Childhood Trauma Questionnaire (CTQ) to evaluate maternal childhood stressful events and the Life-Threatening Events (LTE) to explore traumas during the past 6 months.

Results: For the 125 pregnant women in our study, the mean age was 30 years and 5 months with 99,2% of them married. Mean gestational age was 33 weeks +1 day. PAI's mean score was $55,58 \pm 10,20$; CTQ's mean score was $36,62 \pm 9,53$ revealing trauma in 28%. Women admitted being victims of IPV in 49,6% with almost the half (48,38%) being exposed to two or more forms of violence. Mean score for recent traumatic events in LTE was 1,87 with 65,2% being exposed to two or more life threatening event. A correlation between the total score of PAI and CTQ was found ($p=0.021$) particularly subscales of physical and emotional negligence of the CTQ ($p=0.023$ and $p=0.006$). We found no statistically significant correlation neither between PAI and IPV ($p=0,453$) nor between PAI and LTE ($p= 0,360$).

Conclusions: Providing an appropriate training for health care providers can enable them to detect pregnancies at risk in order to refer them to trauma-informed mental health services.

doi: 10.1192/j.eurpsy.2021.557

Introduction: Autism Spectrum Disorder (ASD), is a neurodevelopmental disorder, characterized by inabilities in communication and social interaction. ¹ Childhood Apraxia of Speech (CAS) is a neurological disorder in which the consistency and precision of speech movements are impaired, in the absence of neuromuscular deficits. ² Research indicates that children with ASD do not have a higher prevalence of CAS. ³ It is suggested that comorbid ASD and CAS would be expected to be extremely rare.

Objectives: Verify the occurrence of CAS in children with ASD.

Methods: The study included 22 children diagnosed with ASD aged between 4 and 8 years, who were undergoing speech therapy at a specialized health service and their therapists. The test was applied by the therapists Differential Assessment of Autism and Other Developmental Disorders (DAADD)⁴, divides into six areas of development: language, pragmatic, sensory, motor, physical and behavioral to differentiate and diagnose disorders of neurological origin.

Results: Among the 22 children participating in the research, 20 did not score the item apraxia. Only two children were referred with apraxia and twelve had receptive language and pre-academic skills proportional to their age. Of 22 participants, only three were overly excited for verbal productions.

Conclusions: The analyzes of data suggests that the occurrence of CAS in children with ASD is low and underlying the disorder.
