Abstract

Community of Practice (CoP) efficiency evaluation is a great deal in research. Indeed, having the possibility to know if a given CoP is successful or not is essential to better manage it over time. The existing approaches for efficiency evaluation are difficult and time-consuming to put into action on real CoPs. They require either to evaluate subjective constructs making the analysis unreliable, either to work out a knowledge interaction matrix that is difficult to set up. However, these approaches build their evaluation on the fact that a CoP is successful if knowledge is exchanged between the members. It is the case if there are some interactions between the actors involved in the CoP. Therefore, we propose to analyze these interactions through the exchanges of emails thanks to Natural Language Processing. Our approach is systematic and semi-automated. It requires the e-mails exchanged and the definition of the speech-acts that will be retrieved. We apply it on a real project-based CoP: the SEPOLBE research project that involves different expertise fields. It allows us to identify the CoP core group and to emphasize learning processes between members with different backgrounds (Microbiology, Electrochemistry and Civil engineering).

Introduction

Knowledge is one of the most valuable resources for modern organizations (Zack, 1999). The efficiency of organizations is strongly linked to the way the knowledge is created, shared, and managed (Nonaka and Takeuchi, 1995; Chu and Khosla, 2009). After (Guptill, 2005) and (Kim *et al.*, 2012), Communities of Practice (CoPs) are particularly effective to consider the whole knowledge lifecycle. CoPs are “groups of people who share a concern, a set of problems, or a passion about a topic, and who deepen their knowledge and expertise in this area by interacting on an ongoing basis.” (Wenger *et al.*, 2002).

In this border, the efficiency evaluation of these groups becomes crucial. Several propositions are worked out in the literature generally focused on the knowledge created and exchanged between the CoPs members. These approaches, as stated in Kim *et al.* (2012), can be grouped into: (i) subjective methods; (ii) objective methods. Generally, these are difficult and time-consuming to apply to real CoPs. For example, the interaction matrix required for SNA (Social Network Analysis) as proposed in Kim *et al.* (2012) takes a lot of time to be built. In this paper, we exploit the analysis of electronic messages exchanged between the members of a CoP to refine the CoPs activities performance evaluation by going beyond the classical evaluation of knowledge sharing level largely studied in knowledge management (Zack, 1999). More precisely, we look for speech acts (Austin, 1975) in the message content to identify, among others, the role of the people involved in the CoP, the knowledge shared and the learning processes that take place between the CoP members. Pragma-linguistics techniques are then applied for this purpose (Levinson, 1983). Another advantage of our approach is that it is systematic and semi-automated.

The paper is structured as follows. The section “State of the art” deals with the state of the art, describing the current approaches for CoPs performance evaluation. The section “Text analysis for CoP performance evaluation” presents the text analysis approach we propose for evaluating CoPs activities. In the section “Case study” the approach we propose is applied on a project-based CoP the SEPOLBE scientific project dedicated to develop bioadmixtures for concrete. The section “Conclusion” concludes and gives further research directions.

State of the art

In this state of the art, we will analyze the different definitions of the CoPs and how the efficiency of CoPs is evaluated.

CoPs definition

In Wenger (1998) CoPs are treated as the informal relations and understandings developed in mutual engagement on an appropriated joint enterprise. In other words, a community of practice is defined as a group that coheres through “mutual engagement” on an “appropriated enterprise”, and creates a common “repertoire”.

In Wenger *et al.* (2002) the concept is redefined towards a more managerial stance, making the concept more popular and simple. Here CoPs are “groups of people who share a concern, a set of problems, or a passion about a topic, and who deepen their knowledge and expertise in this area by interacting on an ongoing basis.” According to Cox (2005), this definition is much vaguer than the previous one. The definition is of a group that is somehow interested in the same thing, not closely tied together in accomplishing a common enterprise. The purpose is specifically to learn and share knowledge, not to get the job done. From this point of view a CoP has three structural features:

- (i) Domain: it “... creates common ground and a sense of common identity. A well-defined domain legitimises the community by affirming its purpose and value to members and other stakeholders. The domain inspires members to contribute and participate, guides their learning, and gives meaning to their actions” (Wenger *et al.*, 2002).
- (ii) Community: it “...creates the social fabric of learning. A strong community fosters interactions and relationships based on mutual respect and trust. It encourages a willingness to share ideas, expose one’s ignorance, ask difficult questions, and listen carefully. Community is an important element because learning is a matter of belonging as well as an intellectual process.” (Wenger *et al.*, 2002).
- (iii) Practice: it “...is the specific knowledge the community develops, shares and maintains” (Wenger *et al.*, 2002).

Considering our objective of a systematic approach based on the e-mail exchanged, we are interested in the practice feature of a CoP that is to say the way knowledge is created, shared, and managed.

Different types of CoPs are identified in the literature. McDermott (2000) indicates four types of community:

- (i) Communities which are linked to a strategic objective;
- (ii) Communities which focus on tactical processes, process optimization, and sharing of best practice;
- (iii) Project-based communities
- (iv) Communities developing a particular body of knowledge.

We are interested in project-based communities. This kind of CoP has several interesting features. First of all, it is confined in time with fix start and end, enabling to study all its lifecycle phases as detailed in Lee *et al.* (2010) from the building stage corresponding to the initial state of a CoP, where people come together and develop a detailed plan of structure of community to the close stage, during which a CoP declines or transforms into several other communities.

Secondly the people involved in the CoP are project members and therefore act actively in the achievement of the project. Their participation degree, as described in Wenger *et al.* (2002), is a core group. A core group is the group of people that carry out the work in the community. It actively participates in discussions and identifies the topics to be addressed within the community. The

coordinator takes place in this group. He/she is the one who organizes events, connects communities and generally keeps the community alive. Moreover, project members are known at the outset enabling to study their mutual interactions easily.

CoP performance evaluation

A CoP is defined as successful when its members exchange specific knowledge, practices and/or experiences that contribute to developing a practice (know-how) in a specific field (McDermott, 2004). The research around the performance evaluation and management of CoPs gains gradually importance. Indeed, in the 90s CoPs were presented as spontaneous, self-organizing, and fluid processes that management cannot intentionally establish (Brown and Duguid, 1991; Lave and Wenger, 1991). In other words, at that time it was considered that the performance of a CoP cannot be measured and managed to improve its efficiency. Later some works suggest that CoPs are amenable to manipulation and can be managed (Wenger, 2000; Wenger and Snyder, 2000; Lesser and Everest, 2001). In turn, as a result of these works, diagnosis frameworks for CoP efficiency management were proposed. These aim at assessing the knowledge creation or sharing level inside a given CoP. To do so, as stated in Kim *et al.* (2012), these frameworks are either based on subjective methods or on objective one. Subjective methods are methods that use qualitative constructs to assess the performance level whereas objective one assess this performance level through a quantitative indicators. In the next subsections we detail two diagnosis frameworks one based on a subjective method (Borzillo and Kaminska-Labbe, 2011) and the second on an objective one (Kim *et al.*, 2012). For each category we analyze its advantages and drawbacks in order to set our research objectives.

CoP diagnosis framework based on subjective methods

In Borzillo and Kaminska-Labbe (2011) the underlying hypothesis of diagnosis is that organizations need to guide CoPs to generate usable knowledge sustainability. As a result, the authors aim to elucidate the related knowledge creation dynamics. Therefore, they go beyond the mere evaluation of the four factors – knowledge objectives, leadership, collaboration, and boundary spanning – that are generally associated with knowledge creation in CoPs. Contrary to this “fragmented” approach, they propose an “integrated” one enabling to understand how the interactions between these factors lead to dynamic knowledge creation processes. To do so, they exploit the complex adaptive system (CAS) theory that provides an integrative and dynamic framework to understand the interaction patterns in networks of interdependent agents who interact and are bound by their common needs or objectives. As a consequence, the four factors of knowledge creation are translated according to the CAS theory lenses into four constructs.

First, the knowledge objectives factor becomes *adaptive tension* that drives self-organization and emergence. It emerges from external constraints and corresponds to the energy differential between the system and its environment. The focus is therefore on the definition of the upper and lower bounds of adaptive tension that will define the “region of complexity” inside which a system is able to create a new order (self-organization) and producing new knowledge (emergence). Second, the leadership factor becomes *enabling leadership*. In this perspective, the managers’ role is to design systems in which distributed intelligence

can easily emerge. For CoPs, enabling leadership means enhancing the socialization between individuals. Third, collaboration becomes *enhanced cooperation*. Indeed, CAS theory emphasizes that knowledge creation depends on the nature of the interactions or connections between agents implying for CoPs regular meetings, workshops, and the enabling information technology for interaction. Fourth, the *boundary spanning* factor remains unchanged. It highlights cognitive diversity for knowledge creation by interacting with actors external to a given CoP.

Then, during 4 years, five CoPs from an international-operating industrial group were studied via a longitudinal exploratory study (six series of interviews) in order to uncover if the four constructs of CAS theory impact positively or negatively the dynamics of knowledge creation. The data gathered were analyzed qualitatively (preliminary analysis for data categorization, within-in community analyses to search linkages between first-order concepts, cross-community analysis to reveal consistencies and contradictions between the CoPs) and quantitatively (average ranking calculation of each constructs). As a result, two modes of CoPs are proposed. Each mode couples two of the four studied constructs (see Fig. 1). When adaptive tension and enabling leadership are prevalent, the CoP is in a “guided” mode. When enhancing cooperation with boundary spanning are prevalent the CoP is in a “self-directed” mode.

These modes are then coupled with knowledge creation processes. The authors argue that a “guided-mode” supports knowledge expansion, while a “self-directed mode” simulates knowledge probing. The guided mode is used to improve the existing product offerings, which requires creating improved knowledge. During the “self-directed” mode, communities explore radically new knowledge.

This study is interesting as it exploits complexity theory to focus on the interaction of the factors leading to knowledge creation in CoP. Even if this link is not formally described, there is generally acknowledged that there is a positive correlation between performance and knowledge creation. However, it seems difficult, on a given CoP, to evaluate the four constructs: adaptive tension, enabling leadership, enhanced cooperation, and boundary spanning. It requires time-consuming data collection [interviews from different informants (community sponsors, leaders, and members); attending to CoP workshops] and data exploitation. Moreover, only two modes are described in this paper the other possible configurations of the constructs are not considered. That is why another research stream explores the use of objective methods.

CoP diagnosis framework based on objective methods

In Kim *et al.* (2012) a framework diagnosis for CoPs is proposed based on SNA (Social Network Analysis). SNA is a scientific method to analyze a social network by focusing on patterns of relationships between actors and examining the availability of resources and their exchange between actors. Here, performance evaluation of CoPs focuses on knowledge sharing activity by providing a view of the relationship network between the members of the CoP that is to say of the knowledge receivers and the knowledge propagators and the related amount of knowledge exchanged as shown in the conceptual framework of Figure 2.

The diagnosis methodology proposed by Kim *et al.* (2012) is the following (see Fig. 3):

1. Pre-process: this step enables to understand the methodology of knowledge sharing and to build the knowledge sharing matrix.

2. Analysis: SNA and development of new indexes for CoP diagnosis;
3. Strategy: suggestion of a strategy for future knowledge sharing activities.

The SNA is based on the knowledge sharing matrix set up during the pre-process step. If the CoP has n members the matrix will be an $n \times n$ size one with each cell filled. The input data are generally retrieved from questionnaires, interviews, and data log, even if other transaction data could be used (online messenger tools, e-mails, etc.). The data processed have to define if two members exchange data or not. For e-mails it requires to identify the sender and the recipients of a given message. It is stated that the working out of this matrix spends tremendous time. Moreover, the kind of questionnaires to use is not detailed.

By using a knowledge sharing matrix for input data, basic indexes can be generated by SNA. Some of the basic indexes are:

- Node type (transmitter or out-flow only node, receiver or in-flow only node, carrier or node with only one connected in-flow, and only one out-flow except from the in-flow node, ordinary or node with a mixed in- and out-flow, isolate or node that is not connected to others);
- Network density that is an indicator for the general level of connectedness of the graph;
- Betweenness centrality: it is the share of times that a node i needs a node k (whose centrality is being measured) in order to reach a node j via the shortest path;
- In and out degree of centrality: it is the proportion of a connected edge to the maximum possible connections.

Based on these indexes the analysis step can be carried out. To do so, the authors provide a member and a CoPs typology. Both typologies are based on knowledge propagating and receiving abilities. There are four kinds of members (see Fig. 4):

- Balanced player: a member who propagates knowledge to and receives knowledge from other members. This kind of member corresponds to the ordinary or carrier nodes;
- Egoistic propagator: a member who propagates knowledge to other members, but does not receive knowledge from other members. Such a member corresponds to the transmitter nodes;
- Egoistic receiver: a member who receives knowledge from other members, but does not propagate knowledge to other members. Such a member corresponds to the egoistic receiver nodes;
- Knowledge isolator: a member who does not propagate knowledge to or receive knowledge from other members. These members are the isolator nodes.

Based on the member typology the CoP typology is set up (see Fig. 5). It is based on the knowledge receiving and knowledge propagating core group ratio that is to say the ratio between the propagators or the receivers and the total number of member in the core group. The core group is identified thank to in- and out-degree centrality. Four communities' types are proposed:

- Active community: the core group has a high ratio of knowledge propagation and receiving;
- Spreading community: the core group has a high ratio of knowledge propagation but a low ratio of knowledge receiving;

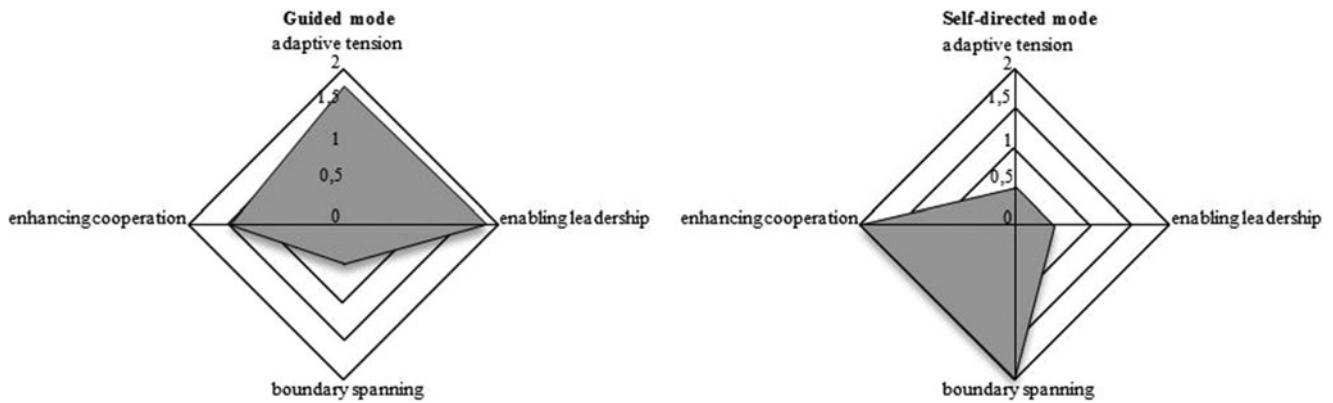

Fig. 1. Guided and self-directed modes of CoPs (Borzillo and Kaminska-Labbe, 2011).

Fig. 2. Conceptual framework of knowledge sharing activity in a CoP (Kim et al., 2012).

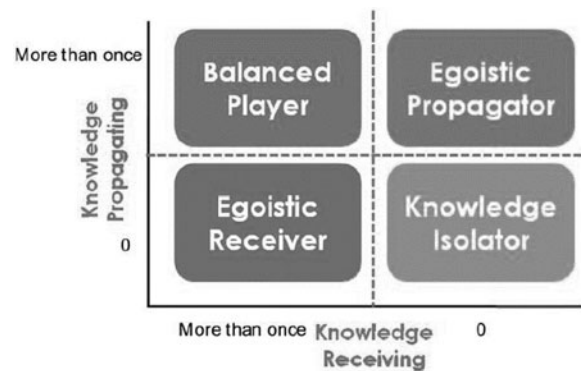

Fig. 4. CoP member typology according to Kim et al. (2012).

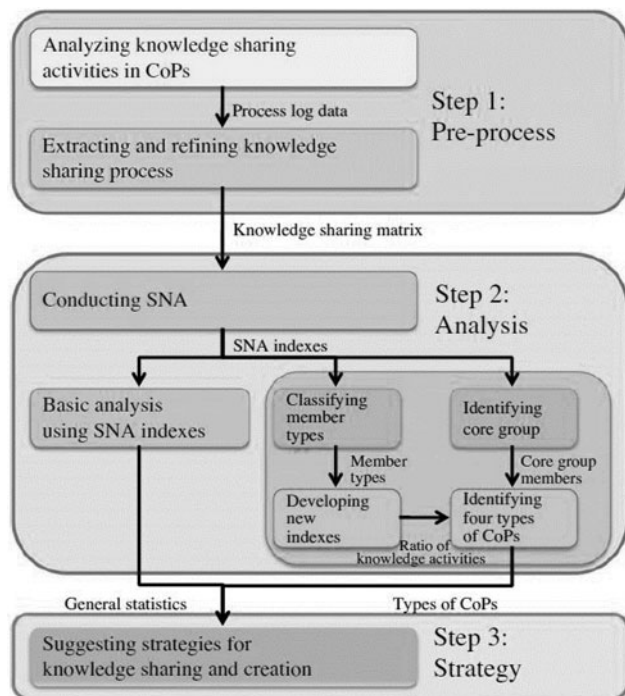

Fig. 3. Diagnosis process of CoPs based on Social Network Analysis (SNA) (Kim et al., 2012).

- Learning community: the core group has a low ratio of knowledge propagation but a high ratio of knowledge receiving;
- Inactive community: this community has low ratios of knowledge propagation and receiving within the core group.

Then, diagnosis of the CoP under study (third step of the framework) is made according to the CoP typology. For each community type improving strategies like, for example, “create more practical knowledge” or “redefine the knowledge domain” are proposed.

This diagnosis framework is complete as it observes a CoP according to knowledge propagating and receiving actions and proposes improving strategies. However, this approach has two main drawbacks. First, the setting up of the knowledge sharing matrix is complex and time-consuming, even if e-mails could be exploited to retrieve the required data automatically. Secondly the diagnosis focuses only on the knowledge exchanges on a binary mode (knowledge receiving yes/no and knowledge propagating yes/no). There is no in-deep analysis of the quality and the type of exchanges that would be interesting to better highlight the CoP performance.

Synthesis

Existing diagnosis methods for CoPs rely on efficiency evaluation on the ability of a CoP to exchange and sustain knowledge over time. However, these are difficult and time-consuming to put into action on real CoPs. They require either to assess subjective constructs, either to work out a matrix of knowledge interaction. In both cases the input data required for evaluation stem from questionnaires and interviews of the members of the CoP.

In Borzillo and Kaminska-Labbe (2011) four subjective constructs (adaptative tension, enabling leadership, enhanced cooperation, and boundary spanning) are evaluated and their

interactions studied. This enables to reflect the way knowledge is created inside a given CoP in a “guided” or “self-directed” mode.

In Kim *et al.* (2012) the members who propagate knowledge and those who receive knowledge are identified and their interactions are analyzed. This enables to evaluate the level of knowledge sharing in a binary manner “Is knowledge exchanged or not between two members?”, then to characterize the CoP members and the CoPs according to their role in knowledge sharing (propagator and receiver) and to last to provide improving strategies for each kind of CoP identified.

The main advantage of the approach of Kim *et al.* (2012) is to evaluate the CoP efficiency in an objective manner, even if the indicators proposed are binary and do not reflect as it is the case for Borzillo and Kaminska-Labbe (2011), the complexity of knowledge sustainability. In our view, the objective method option such as proposed in Kim *et al.* (2012) is the most promising because it ensures the reliability of the evaluation. However, it could be improved and completed with a semi-automated analysis of the content of the knowledge shared as well as the related intentions of the actors. In this way, the nature of the knowledge shared can be identified so as the contribution of this sharing to organizational learning by identification of the learning processes involved and the role of the actors in the CoP. For this purpose, our approach looks for the impacts of interactions on the CoP users and their organization by analyzing communication.

There are different kinds of techniques to analyze communication [as TextMining, Natural Language Processing (NLP), etc.]. On the one hand, TextMining groups a set of techniques enabling to extract information from documents. On the other hand, NLP is the field of study that focuses on the interactions between human language and computers. Both approaches do not enable to emphasize the interactions between actors that is the main feature of knowledge sharing and learning evaluation in CoPs. Therefore, we use the Pragmatics approach because that helps to analyze the content of communication and to identify the intention of interactions between participants. We present in the next section this type of analysis.

Text analysis for CoP performance evaluation

Communication analysis

Several approaches study how to analyze communication as a specific discourse. We note for instance, tagging work in Yelati and Sangal (2011), in which the authors present techniques that help to identify topics in e-mails. We also note NLP (Natural Language Processing) community on automated speech act identification in emails (Baron, 1998; Corney *et al.*, 2002; Carvalho and Cohen, 2006). For instance, Kalia *et al.* (2013) use NLP in order to identify messages concerning tasks and commitment. They parse verbs and sentences in order to identify tasks and track messages between senders and receivers. Pragmatics, the study of language in use, is concerned with the intended meaning of speakers beyond what is explicitly stated. It is a branch of linguistics concerned with the use of language in social contexts and the ways in which participants produce and comprehend meanings through language. Pragmatics focuses on aspects of signification that are not only predicted by linguistics knowledge. It is concerned with the analysis of the speaker’s meaning rather than on the meaning of words and utterances (semantic or linguistic meaning). Thus Pragmatics takes into account the role of physical and social context (Austin, 1975). Pragmatics analysis

of communication using e-mails uses only some of these methods like ngrams analysis by Carvalho and Cohen (2006), Verbal Response Mode scheme by Lampert in Lampert *et al.* (2010) or a custom coding scheme like in Felice and Deane (2012).

As cited above, we use Pragmatics in order to study communication in the community of practices and topic identification. Our aim is first to identify if contributors learn from each other’s and on which topics. So, we apply the CaMca “Context aware Mediated Communication analysis” approach (Rauscher *et al.*, 2016), we develop for this aim. CaMca is based on Pragmatics analysis and context awareness. So, it helps to identify, from one side, intention of communications and from another side, links interactions to the activity context. CoPs activity evaluation needs these dimensions because participants activities and roles are important. As the analysis is context dependent, it makes no sense to study a big volume of interactions such as in SNA. The objective differs from SNA for e-mails and that could be used to improve the CoP diagnosis framework of Kim *et al.* (2012). Indeed, as detailed in Tang *et al.* (2014) SNA for e-mails is generally used for contact identification focusing on the structure of the network built from the email corpus and paying less attention to email contents.

CaMca approach

Pragmatics puts on the fact that a dialogue is context and time-dependent. Identifying the sense of interaction is related to the conditions, environment and situation of communication. We develop the CaMca approach that considers from one side the context and the domain of the activity and from the other side the speech acts in mediated communication.

The different phases of this approach are (Rauscher *et al.*, 2016) (see Fig. 6):

- Context identification:
 - Skill and role of actors;
 - Phases of collaboration among time;
 - Goal of collaboration.
- Domain identification
 - Domain topics and subjects.
- Communication analysis
 - Sender/receivers/CC;
 - Date/Hour;
 - Subject;
 - Thread of communication: Reply, comments;
 - Main Speech Acts.

Each phase of CaMca will bring a piece of information about CoP activity. Indeed, the context identification is useful to underline the actors’ skills and collaboration roles corresponding to the “Community” feature of a CoP as described in the section “CoPs definition” This enables to identify the core group and the coordinator of the CoP under study. The domain identification will be used to identify the topics on which the CoP exchanges, enabling to define the nature of knowledge shared. That is the “Domain” feature of a CoP. Last but not least the Mediated Communication Analysis focuses on the e-mail exchanged enabling to assess the degree of knowledge sharing and interactions between CoP participants (“Practice” feature) and the related knowledge processes that take place.

In fact, in context we try to identify the organization of the communication. It mainly concerns actors and their collaboration goals. The domain analysis puts on, the nature of the activity

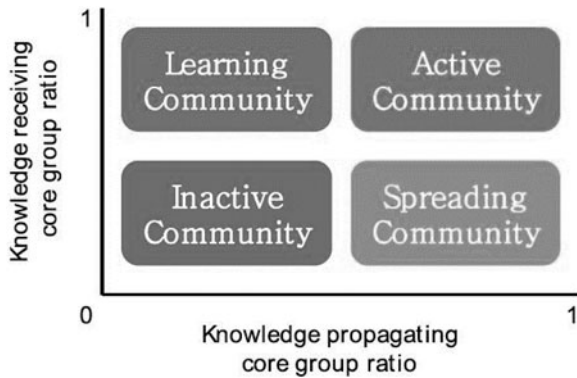

Fig. 5. CoP typology according to Kim *et al.* (2012).

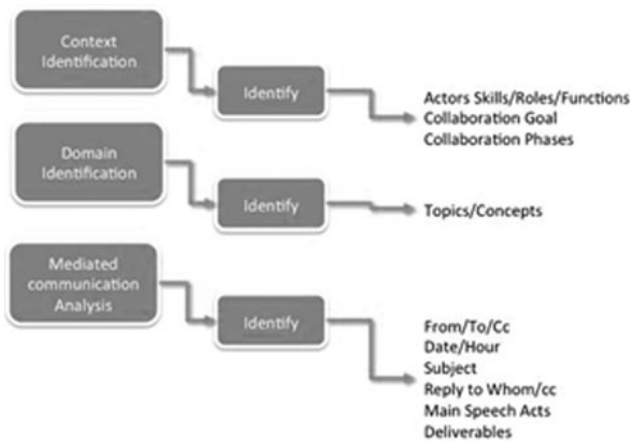

Fig. 6. CaMCA basic approach.

subject of interactions, on which practices participants discuss. Finally, the analysis of communication helps to emphasize the real effects of interactions: what happened when actors received and post messages? Is there any learning, coordination, conflict, alliances, etc? And how it is done? CaMCA is used in order to identify the nature of interactions in CoPs. Then the results obtained can be compared to the CoP typology depicted in Figure 4. In this way, the performance and diagnosis of studied CoPs can be put on in a systematic way.

So, we propose to apply CaMCA to a project based CoP. Interaction around a project is analyzed and first principles of systematic CoPs diagnosis approach is determined. These principles are identified by analyzing the communication of the real SEPOLBE project, presented in the next section.

Case study

In this section, we will illustrate the use of CaMCA on a project-based CoP. We will analyze the exchanges between the members of the Cop. The roles of the actors, particularly the coordination, will be analyzed. The knowledge exchanged and created will also be studied.

Study context: the SEPOLBE project

We apply the CaMca approach to the SEPOLBE research project in order to identify the knowledge shared and the learning processes that take place between the members and to analyze how

Table 1. Main speech acts related to learning communication

Speech acts	Example of verbs
Information	Inform, Send, ...
Explication	Explain, Clarify, Precise, Propose
Evaluation	Agree, Refute
Description	Describe, Detail, Can, Propose
Request	Verify, Ask, Wonder, Would you, Could you

the CoP is coordinated (Who is the coordinator?; Level of coordination). The SEPOLBE project is dedicated to develop bioadmixtures for concrete (Goepf *et al.*, 2014). These substances are conscientious of the environment and should limit the biocontamination of the concrete surface and improve the resistance to corrosion of its metallic reinforcement. This project implies four research teams and a company. The research teams have different complementary areas of competency: concrete surface analysis, physical chemistry analysis of films on steel and concrete, electrochemistry for steel corrosion inhibition, petrophysics for concrete physical chemistry characterization. Competences in microbiology, chemistry, and microscopy are also required to develop the substances and to analyze the surface biocontamination. The industrial partner manufactures and markets concrete products such as admixtures. Its product mix already includes protection products but none of them is dedicated to biological contamination. The duration of this project is about 4 years. Actors come from three main domains: Microbiology, Electrochemistry, and Civil engineering. To show the applicability of our approach, we focus on two tasks of the project: (i) Project coordination and (ii) Assessment of the cleaning ability of the mortar base surfaces. Here, the objective is to evaluate the ability of the bioadmixtures to limit the development of biofilms on the concrete surface and its impact on the cleaning concrete surface (biofilm dropping out). The ICube and B2HM teams are in charge of this task. The ICube team has to provide to the B2HM team “adequate” concrete samples. The B2HM is in charge of the contamination and cleaning tests.

For these tasks we analyze the e-mail exchanges between the people involved in the task. The people involved provided us the e-mails they received and sent to complete a given task (coordination or cleaning ability evaluation). So, we had access to the e-mails as a whole (sender, recipients, date, content, etc.)

Learning evaluation using E-mail analysis

The main topics of the task dealing with the assessment of the cleaning ability of the mortar base surfaces concern: Concrete, Mortar, Sample, Bioadmixtures (or BA), Molecular, Bacteria, Essay, Experiment, Polishing, Sample, Ultrasonic, etc.

Actors communicate together using mainly e-mails but if the content of message is available other sources of electronic messages could be exploited such as forums could be exploited. So, we analyze their communication in order to understand if there was any learning of procedures or concepts. First of all, our expert on Pragmatics identifies a grid of main speech act types concerning learning (see Table 1).

Then, based on different synonyms and sentence forms given by the pragmatics expert and the list of project topics, the NLP algorithm (Lucen) has been used in order to retrieve the

Fig. 7. Results of NLP analysis.

Table 2. Communication between actors for procedure clarification

Date	Sender	Skill	Receiver	Subject	Speech Act	Sentence
20/12/12 11:44	Charlotte	Civil engineering	To: Thierry	Subject: bioreceptivity Experiment	Request	Can you explain the Bioadmixture experiment you do on samples of concrete: conditions of essai...
11/02/13 15:27	Thierry	Microbiology	To: Charlotte	Subject: bioreceptivity Experiment	Proposition, Explanation	We propose to proceed in two times: Short one depending on Samples receiving time and a long one (after a cure time) in order to detect aging of samples and biofilms development

corresponding messages. Figure 7 illustrates the global results obtained. The inside wheel shows the topics identified and the outside wheel the corresponding speech acts.

In our analysis, we try to identify if there is learning of concepts or procedures. So, we look for some specific speech acts like proposition, explanation, request, verification, and information. Then we study this type of interaction among time: at the beginning, in the

middle, and at the end of task and project. For instance, at 20/12/12 Charlotte “civil engineer” asks about the Bioadmixture experiment conditions needed. Thierry “Microbiologist” answers her by explaining a procedure (see Table 2).

At 21/03/13, some months after this interaction, Charlotte “civil engineer” presents some modification on the procedure (see Table 3).

Table 4. Procedure verification about sample conservation

Date	Sender	Skill	Receiver	Subject	Speech Act	Sentence
10/04/13 14:38	Charlotte	Civil engineering	To: Chao, Thierry	Subject: Sample Conservation	Request Verification	I need to verify some elements in the procedures of the samples treatment.
15/04/13 14:58	Thierry	Microbiology	To: Charlotte	Subject: Sample Conservation	Explanation	Right, we need to respect the same conditions for sample treatment... below, you find all precisions on sample treatment...

The text in bold indicates the verb that enables to define the kind of request.

Table 5. Verification of the procedure for sample shipping

Date	Sender	Skill	Receiver	Subject	Speech Act	Sentence
21/06/13 15:43	Charlotte	Civil engineering	Chao	Samples treatment	Request Verification	I want to be sure about the modification of the procedure... I turned out the samples, I stored them in filtered water Tomorrow I will polish them, treat them with Uvs and I will send them to you.

The text in bold indicates the verb that enables to define the kind of request.

Table 6. Coordination of main speech acts and topics

		Request	Meeting Date	Could you also give me a date between 12 and 14 September for a meeting.	Could you also give me a date between 12 and 14 September for a meeting.
	Bernard	Information	Meeting Date and Place	The first meeting date will be held on Monday 17 September at LISE.	The first meeting date will be held on Monday 17 September.
		Request	Participation	Please confirm your participation	Please confirm your participation
		Proposition	Meeting Schedule	I propose the following Meeting Schedule	I propose the following Meeting Schedule

We suppose then that Charlotte learns the procedure, uses it, and tries to adapt it to specific conditions.

At 10/04/13, Charlotte asks for more verification about the samples conservation and Bioadmixture test conditions of sample treatment. Chao and Thierry define more specifications about these conditions (see Table 4).

Charlotte asks then more verification about the procedure she applies (see Table 5).

We suppose that among these interactions, actors learned from each other about bioreceptivity mixture experiment and sample treatment and conservation. Other analysis of messages show also interactions about samples' name coding and sending modes.

The chronology of interactions proves their dynamicity especially if actors have a timeline to respect, they communicate about the project phases.

Coordination analysis

Using CaMca approach, e-mails are also analyzed in order to analyze how the CoP is coordinated. For this purpose, our analysis is based on coordination intentions (Matta *et al.*, 2011). A specific grid was defined containing speech acts related to coordination and topics concerning the coordination (see Table 6). The main coordination speech acts are about information, proposition,

Table 8. Summary of interaction analysis

Sender	Speech act	Topic	Number
Francoise	<i>Information</i>	Project Documents	8
		Meeting Report	5
		Project Presentation	2
		Meeting Date, Place	2
		Meeting logistics	2
	Total		19
	<i>Proposition</i>	Meeting Date, Place	7
		Project Presentation	3
		Meeting Scheduling	7
	Total		17
	<i>Request</i>	Meeting Date, Place	6
		Meeting Report	2
		Meeting Scheduling	1
		Meeting logistics	2
		Project Documents	3
		Project Presentation	3
		Total	
Bernard	<i>Proposition</i>	Meeting Date, Place	1
		Meeting logistics	1
	Total		2
Anouk	<i>Request (Total)</i>	Meeting logistics	3
	<i>Information (Total)</i>	Meeting logistics	1
Thierry	<i>Request (Total)</i>	Meeting logistics	2
	<i>Request (Total)</i>	Meeting logistics	1
Thierry, Isabelle, Sandrine, Anouk, Sebastien, Virginie	<i>Information (Total)</i>	Meeting Participation	7

and request. Topics are around meetings, documents, and reports. A statistical analysis is also done in order to identify the engagement of actors in interactions. This type of analysis can complete those done by SNA in Kim *et al.* (2012), especially the CoPs users behaviors studied. Adding to statistical studies of exchanges, the

identification of the interaction roles as used in our study help to emphasize the dynamic organization movements.

In total 42 messages have been analyzed using this grid and based on the CaMca approach. These messages correspond to four milestones of the projects: Kick off, 12th, 18th, and 30th month. Message date, Senders, Receivers, speech acts, topics are identified. A total of 101 important sentences are identified from these messages. Table 7 illustrates a part of the analysis for the Kick off milestone.

First statistics analysis synthesized in Table 8 shows that Francoise is the main animator of the group. She takes the role of animator of coordination. She is the author of 22 messages. In these messages, Françoise informs about project documents, meeting reports, and meetings logistics (19 speech acts), proposes meetings schedules and project presentations (17 speech acts) and asks for modification on Meetings Reports, logistics, and project documents. We observe also the dynamic participation of other actors like Bernard (Two speech acts on Information and one on Request about Meeting logistics) and Anouk (one speech act on Information and one Request about Meeting logistics) in the organization of meetings.

Finally, even messages are addressed to all participants of projects (16 participants), only seven participate in the discussions. Time interaction analysis shows that messages are close to meetings dates.

As showed in this analysis, CaMca can be used to identify the nature of animation of CoPs and the core group. In SEPOLBE, we can see that some actors are engaged in the animation of CoPs and form the core group that is essential for a successful CoP. The animation is dynamic around meetings and tasks deadline. Besides that, interactions concern explanations of procedures and precision of techniques.

Discussion

We focus on this paper on a systematic and semi-automated analysis of CoPs that goes beyond knowledge sharing level assessment. Our analysis technique is based from one side on interaction content analysis and from the other side on participants' competencies. This technique is summarized in Table 9.

The analysis of the SEPOLBE project interactions shows that we can answer to some characteristics of CoPs using CaMca approach especially (see Table 10). So, in the SEPOLBE project there are two interaction sequences about Bioreceptivity Experiment and Samples Conservation that show learning between Charlotte and Thierry. The close dates of interactions can emphasize an active community but only 40% of participants send messages and only 18% are involved in coordination. So, we can note that only 40% of the community is active and 50% of coordination messages emphasize the cooperation dimension of the CoPs.

Francoise can be identified as the coordinator because she is implied in 22 messages using propose and request speech acts. Finally, we can note that the effective participants are a balanced player; all participants are in copy of messages or as receivers, even when there is some dialogue between Charlotte and Thierry (see Table 10).

As shown in this paper, combining messages analysis and context awareness can give a technique to go beyond the classical knowledge sharing level assessment of CoPs. We tend in our analysis to identify a systematic methodology that helps to diagnosis CoPs. This methodology is based on intention identification principle (Richard, 1990), which shows that a sense interpretation is

Table 9. Our analysis technique

	Learning	Coordination/Engagement
Parameters	Speech Acts: Explanation, Request, Verification, Evaluation	Speech Acts: Inform, Propose, Request
	Participants' Competencies	Animation subjects
	Main Topics of CoPs	Sender- Receivers
	Date of Interaction	Date of Interaction
Method	Identification of Speech Acts on messages related to specific sentences	Identification of Speech Acts on messages related to specific Sentences
	Description of Participants Competencies from participants presentation	Identification of Animation objects from messages
	Identification of main topics of CoP from CoP presentation, linking message to main topics	Identification of Senders/Receivers
	Linking Topic-speech act- competences - Date	Linking sender to Speech Acts and object
		Count messages related to Senders/Speech acts and objects
Analysis	For each topic:	For each sender:
	- Analyze iteration sequence of :	- Analyze frequencies sequences of:
	- Explanation	- Object
	- Request	- Proposition/Information
	- Verification	- Request
	- If different competencies of messages senders then	- Answer-sender-date
	- Suppose learning between participants	
		- If frequencies of sequences are important then the Sender play animator role for the object
		- If Answer-sender-date is close to animator messages then the animation is dynamic
		- Compare senders and message Receivers :
	- Messages Receivers do not interact then related CoPs participants are not engaged	

linked to action and environment. We used an approach mixing statistics and content analysis. We succeeded in identifying the real coordinator of the CoP and how the actors learn from each other thanks to the emails exchanges.

Conclusion

CoP efficiency evaluation is a great deal in research. Indeed, having the possibility to know if a given CoP is successful or not is essential to better manage it over time. The existing approaches for efficiency evaluation are difficult and time-consuming to put into action on real CoPs. They require either to evaluate subjective constructs making the analysis unreliable, either to work out a knowledge interaction matrix that is time-consuming to set up.

These approaches build their evaluation on the fact that a CoP is successful if knowledge is exchanged between the members but they focus evaluation on the level of knowledge shared and created. This is useful but partial. Indeed, when knowledge is shared there are some interactions between the actors involved in the CoP. Therefore, we propose to analyze in detail these interactions through the exchanges of emails thanks to NLP. Our approach is easy to put in action as it is systematic and semi-automated. It requires the e-mails exchanged and the definition of the speech-acts that will be retrieved. Our approach allowed us to identify one of the key roles of a project-based CoP: the leader of the core group. We also succeeded in identifying the learning process during the project between stakeholders from different domains: civil engineering and biochemistry. These first

Table 10. Characterization of CoPs using CaMca approach

		SEPOLBE analysis	
		Subject : bioreceptivity Experiment	Samples' Conservation
Learning Community	Repeating Sequence: Explanation, Request, Verification, Evaluation	20 dec. Charlotte: Request / 11 Feb. Thierry: Explanation / 11 Feb. Thierry: Request / 11 Feb. Charlotte: Explanation / 21 Feb. Thierry Explanation / 21 Mar. Charlotte: Explanation	10 Apr. Charlotte: Verification / 10 Apr. Charlotte: request / 15 Apr. Thierry: Explanation / 21 June Charlotte : Verification
	Different competencies of Interactions' participants	Charlotte: Civil engineering / Thierry: Microbiology	
Active Community	Close date of interactions	Discussions around 2 or 3 months	
	Important volume of interactions	about 30 messages per year	
	Answers from the majority of participants	40% active participants	
	Participants involved on coordination	18% participants involved on coordination	
Enhancing cooperation	Important volume of coordination messages	50% coordination messages	
Enhancing Learderships	Sender using a lot of Propose, Request speech acts	Francoise: 22 messages	
Balanced Player	Messages sent to all participants	Messages sent to all participants or CC to all participants	

promising results must be confirmed on other project-based CoPs but also on other types of CoPs for instance to study problem-solving exchanges, experts identification, etc.

Last but not least it would be interesting to couple the proposed approach general guidelines of CoP management as they are proposed in Probst and Borzillo (2008) or Jeon *et al.* (2011). Indeed, in Probst and Borzillo (2008) the most salient reasons for the success and failure of CoPs are worked out. An investigation on 57 CoPs from major European and US companies led to the discovery of ten “commandments” that lead to the successful development of CoP. These ten “commandments” describe CoP governance practices and could be linked with CoP diagnosis in order to apply the “commandments” that the best fit to a given CoP context. Jeon *et al.* (2011) identify and validate a set of organizational factors that was anticipated to have effects on knowledge sharing by CoP members such as perceived consequences, affect, social factors, and facilitating conditions. According to a given CoP diagnosis the corresponding organizational factors could be put into action.

- Virginie Goepp** is an associate professor with ability to supervise PhD at INSA Strasbourg, France. Her current research interests include the design and management of technical information systems with an enterprise engineering and modeling perspective. Particularly, she is interested in the alignment between these systems and the enterprise seeking to provide efficient use of ITs. Currently she is deputy head of the Design, Information System and Production team of ICube.
- Nada Matta**, Professor at the University of Technology of Troyes, studies techniques in knowledge engineering and management, to handle cooperative activities as product design. Currently, she is Director of the “Human, Environment and ICT” department. She assumed several responsibilities as: Director of “Scientific group of supervision, and security of complex systems” for 5 years and Director of Department of “Information Systems and Telecom” for 2 years. She defended her PhD in knowledge engineering and Artificial Intelligence at University of Paul Sabatier in collaboration with ARTEMIS. She also worked for 4 years at INRIA in projects with Dassault-Aviation and Airbus Industry.
- Emmanuel Caillaud**, Full Professor at the Université de Strasbourg, France since 2002. He received a PhD in mechanics from Université de Bordeaux, France in 1995. He assumed several responsibilities as dean and pro-vice chancellor in charge of academic affairs. His research interests include knowledge-based engineering, sustainability, and systems engineering.
- Françoise Feugeas**, civil engineer and Full Professor at INSA Strasbourg. After her PhD in material science in 1998, she directed a team for the development of the research axis “Materials Biodeterioration”. She assumed responsibilities as co-head of the civil engineering team of ICube laboratory and nowadays she is Chair of the Committee “Biodeterioration of Materials” of CEFRACOR, Head of the transverse axis “Engineering of Materials for Energy and Environment (IMEE)” of ICube, Responsible for the “Materials, Environmental and Sanitary Impacts” axis of the GC-E team.
