Introduction: Tuberculosis is a bacterial infectious disease caused by *Mycobacterium tuberculosis*. This disease predominately affects the lungs but also affects other parts of the body, including the central nervous system. According to the the World Health Organization (2023), tuberculosis has an incidence of 6.4 million people in 2022, with 1.5 million deaths attributed to this disease. Psychosis describes a group of disorders that affects a person's thought process and perception. It is a serious disorder that can have a profound impact on a person's mental and physical health. As a result, psychosis symptoms and its treatment can complicate the management of tuberculosis.

Objectives: The aim of this systematic review is to explore the association between tuberculosis and psychosis. It has been shown that up to 70% of patients with tuberculosis also have comorbid mental illness, this is likely to include psychosis. There are also shared risk factors between tuberculosis and psychosis, including poverty and homelessness, substance abuse, HIV positive serology and isolation. Tuberculosis medication, including isoniazid and rifampicin have been shown to have adverse psychiatric effects and we will examine if this includes psychosis.

Methods: A systematic review was pre-registered with PROSPRO and performed using Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. MEDLINE, OVID and PsychINFO databases were searched from beginning of records to September 2023. This included hand-search of relevant reference lists. Observational and epidemiological studies were included along with population based registries.

Results: Over one thousand (1,154) articles were identified and screened. There was significant heterogeneity in results and over half of studies were from Asia and Africa. Many studies reported cases of drug-induced psychosis from anti-tubercular agents. Studies also discussed the increased risk of TB incidence among patients with psychosis and other psychiatric disorders.

Conclusions: This study identifies the importance of training healthcare workers in rapid detection of co-morbid psychosis in patients with tuberculosis, along with neuropsychiatric side effects of antitubercular agents. Integration of psychiatric and medical care of these patients would be of benefit to improve outcomes in this patient population. More research is needed on co-morbidity of tuberculosis and psychosis.

Fibronectin as a Marker of Myocardial Remodeling in Patients with Depression and Chronic Heart FailureA. K. Sikora^{1*} and S. Fedorov²¹Psychiatry, Narcology and Medical Psychology and ²Ivano-Frankl'skenderun National Medical University, Ivano-Frankivsk, Ukraine

doi: 10.1192/j.eurpsy.2024.760

Introduction: Depression is a significant issue in chronic heart failure (HF), with a prevalence of about 20–40%, which is 4–5% higher than in the general population (Mbakwem A., et al., 2016).

Objectives: The purpose of this study was to evaluate plasma fibronectin levels in patients with depression and chronic heart failure.

Methods: A total of 80 patients with HF II-III NYHA classes due to chronic coronary artery diseases (CAD) were observed. All patients were divided into two groups: Group 1 - 20 individuals without signs of depression, and Group 2 - 60 individuals with depression. The diagnosis of HF was confirmed based on ESC guidelines (2021). Depression was diagnosed using several questionnaires (Zung Self-Rating Depression Scale, Beck Depression Inventory, Hamilton's Depression Scale). Standard laboratory and instrumental tests were conducted. The plasma levels of fibronectin and interleukin-1 β (IL-1 β) were identified using ELISA methods. Statistical analyses were performed using Statistica system software, version 12.0.

Results: The average plasma fibronectin concentration in patients with depression and HF was 1.24 times higher than a similar indicator in HF patients without depression: (259.63 \pm 5.71) μ g/ml versus (203.41 \pm 9.51) μ g/ml (p <0.05). The conducted correlation analysis indicated a moderate positive correlation between the level of fibronectin and the number of neutrophils in peripheral blood (r =0.35; p <0.05), the level of fibronectin and the magnitude of endogenous intoxication according to the erythrocyte absorption ability test (r =0.44; p <0.01), the level of fibronectin and IL-1 β concentration (r =0.39; p <0.05), and an inverse correlation with left ventricle ejection fraction (r =0.32; p <0.05).

Conclusions: Thus, the plasma fibronectin content in patients with depression and ischemic HF serves as a marker of the progression of myocardial remodeling processes and the intensity of the inflammatory process.
