Four multidisciplinary oceanographic surveys were conducted in November and December from 2007 to 2010, along the Mauritanian coast (NW Africa). A total of 10,514 brachyuran crabs belonging to 33 species were captured in 316 hauls at depths between 79 and 1867 m. The most specious family was Inachidae represented by nine species; the remaining 24 species belonged to 16 other brachyuran families. *Monodaeus cristulatus* is reported for the first time since its original description. Seven other species, *Ethusa rugulosa*, *Pseudomyra mbizi*, *Inachus grallator*, *Macropodia gilsoni*, *Macropodia hesperia*, *Solenolambrus noordendei* and *Spinolambrus notialis* extend their range of distribution northwards and, together with *Goneplax barnardi*, are reported here for the first time in Mauritanian waters. New data about depth ranges are reported for *Acanthocarpus brevispinis*, *Ethusa rugulosa*, *Inachus aguiarii*, *Inachus grallator*, *Inachus nanus*, *Macropodia macrocheles*, *Solenolambrus noordendei*, *Spinolambrus notialis*, *Liocarcinus corrugatus* and *Monodaeus cristulatus*. New data relating to the spawning period for most of the species are also included, as are some biogeographic and bathymetric considerations about brachyurans studied in the area.

Keywords: Brachyura, deep-sea, Mauritanian waters, distribution, new records

Submitted 27 February 2015; accepted 5 April 2016; first published online 18 May 2016

INTRODUCTION

The infraorder Brachyura is regarded as the most diverse taxon within the Crustacea, with more than 6500 species (de Grave *et al.*, 2009) related to 102 families (Ahyong *et al.*, 2011).

The brachyuran fauna from the north-eastern Atlantic, and especially from European coasts, is currently one of the best known worldwide. The knowledge on diversity and distribution of decapod fauna in this region was summarized by d'Udekem d'Acoz (1999). Further publications, mostly focused on the Mediterranean Sea, provided new information on bathymetry and/or biogeographic distributions of decapods (Maynou & Cartes, 2000; Sánchez-Jerez *et al.*, 2000; Modena *et al.*, 2001; Abelló *et al.*, 2002; Pipitone & Arculeo, 2003; Company *et al.*, 2004; Politou *et al.*, 2005; Ungaro *et al.*, 2005; Ateş *et al.*, 2006; Fanelli *et al.*, 2007; Pipitone & Vaccaro, 2011; El Lakhrach *et al.*, 2012), or information related to new findings or the biology of a particular brachyuran species (Mura & Cau, 2002; Giacobbe & Spano, 2006; Rossetti *et al.*, 2006; Guerao & Abelló, 2007; Mavidis *et al.*, 2008; Isajlović *et al.*, 2009; Massi *et al.*, 2010; Neudecker *et al.*, 2011; Capezzutto *et al.*, 2012; Porporato *et al.*, 2012).

However, where West Africa is concerned, the only comprehensive monographs on brachyuran crabs are those by Monod (1956) and Manning & Holthuis (1981). In addition,

some local studies on crustacean or decapod fauna were also undertaken along the West African coast, the most representative being those by Barnard (1950, 1955) in South Africa; Macpherson (1983, 1991) in Namibia; Henriksen (2009) in the Gulf of Guinea; Muñoz *et al.* (2012) in Guinea-Bissau; Fransen (1991) in both the Canarian-Cape Verdean Region and the Banc d'Arguin (Mauritania); Anadón (1981) in northern Mauritania and south-western Sahara; González Pérez (1995) in the Canary Islands and García-Raso (1996) in Ibero-Moroccan waters. All these works include citations for brachyurans and collectively have improved the knowledge of this group. However, no other references focus particularly on Mauritania other than a succinct list of brachyurans (Monod, 1933) and some scant records (Monod, 1956; Anadón, 1981; Manning & Holthuis, 1981; Fransen, 1991).

From 2007 to 2010, the ECOAFRIK project, led by the Spanish Institute of Oceanography (IEO), in collaboration with the University of Vigo (Spain), carried out four annual multidisciplinary surveys in Mauritanian waters (MAURIT surveys). This work presents the taxonomic results for the deep brachyuran fauna and is the first contribution associated exclusively with this group in waters off Mauritania. We also provide new data about the geographic distribution, bathymetric range and spawning periods for some of the species studied.

MATERIALS AND METHODS

The MAURIT surveys were conducted annually from 2007 to 2010 onboard the Spanish RV 'Vizconde de Eza' along the

Mauritanian coast ($16^{\circ}05'49''\text{N}$ $20^{\circ}48'13''\text{W}$, see Map 1) in November–December.

A total of 316 stations were sampled at depths between 79 and 1867 m by means of two different bottom trawl gears. A total of 291 stations were sampled with a commercial trawl (Lofoten type, coded MU), following a stratified random sampling procedure. Another 25 stations were sampled with a 3.5 m beam trawl (coded MUBV) along five transects perpendicular to the coastline in five bathymetric strata (150, 300, 500, 1000, 1500 m), distributed along the Mauritanian coast (see Map 1). Station data, including coordinates, depth, date and collected species, are summarized in Table 1.

Samples were sorted and identified onboard to the lowest taxonomic level. For each species all the specimens were counted, weighed and pictured. A representative collection of each station and of each species was preserved in 70% ethanol and stored for further studies in the laboratory.

The classification adopted in the present work follows Ahyong *et al.* (2011) to the family level, and genera assignments follow de Grave *et al.* (2009). Subsections, superfamilies, families and species are usually listed in alphabetical order.

For each species we provide some relevant literature references, including those with the descriptions of the species that best fit with our specimens. We also provide the material

Map 1. Sampling area showing the location of the MAURIT stations with presence of brachyurans.

Table 1. Data of the MAURIT stations: date, coordinates, bathymetric range and captured species.

examined (with additional material for some species), mention of the station code, the depth range and the number of specimens captured, in parentheses. As a measurement of specimens, we used the carapace length (CL), measured along the dorsal midline, from the base of rostrum to the posterior margin of the carapace. This measurement was obtained for males, females and ovigerous females, or combinations of all three, when appropriate. We also summarize the biological features and geographic distributions (mainly those published in the last 30 years), including the new data reported with this work, along with some remarks when required. In addition, we include pictures, mostly taken onboard when captured, of each species described.

In the laboratory, pictures were taken with a motorized Nikon SMZ25 stereomicroscope, using NIS-Elements Microscope Imaging Software, with an Extended Depth of Focus (EDF) patch.

The specimens examined for this work are largely deposited in the collections of the University of Vigo (Spain) (Marine Zoology Laboratory) and at the Oceanographic Centres of the Spanish Institute of Oceanography (IEO) in Cádiz (Collection of Decapod and Stomatopod Crustaceans, CCDE-IEOCD) and Málaga (The Marine Fauna Collection, CFM-IEOMA).

Abbreviations used are: ICMD: Biological Reference Collections samples code of the ICM-CSIC (Instituto de Ciencias del Mar-Consejo Superior de Investigaciones Científicas), Barcelona, Spain; USNM: United States Natural Museum, Smithsonian National Museum of Natural History, Washington, USA; IEO-CD: Instituto Español de Oceanografía, Centro Oceanográfico de Cádiz, Spain.

Family HOMOLIDAE de Haan, 1839

Genus *Homola* Leach, 1815

Homola barbata (Fabricius, 1793)

(Figure 1)

Cancer barbatus Fabricius, 1793: 460.

Homola barbata: Guinot & Richer de Forges, 1995: 323 figs. 1A, 7A, B, 8a, b, e, 9a, 13a (references).

MATERIAL EXAMINED

MU87, 271–305 m, (2); MU88, 94–120 m, (1); MU119, 82–80 m, (1); MU120, 109–105 m, (1); MU122, 82–80 m, (1); MU128, 218–404 m, (1); MU131, 102–104 m, (1); MU158, 80–98 m, (1); MU162, 148–149 m, (1); MU184, 213–202 m, (1); MU186, 174 m, (1); MU200, 352–334 m, (7); MU204, 155–145 m, (1); MU223, 116–117 m, (2); MU281, 100–106 m, (1); MUBV02, 318–330 m, (1); MUBV21, 107–109 m, (1).

Males: 12.78–14.51 mm, females: 12.77–23.30 mm, ovigerous females: 15.53–21.11 mm.

Fig. 1. *Homola barbata* (Fabricius, 1793), ovigerous female CL: 21.11 mm dorsal view, MU281.

IDENTIFICATION

Our specimens agree well with the description provided by Manning & Holthuis (1981: 25) and González-Gurriarán & Méndez (1986: 59).

BIOLOGY

A photophilic and sciaphilic species (Pipitone & Vaccaro, 2011) previously cited from bottoms of mud, mud with rocks, muddy sand, muddy shells, seagrass, rocks and sometimes in caves (d'Udekem d'Acoz, 1999; Pipitone & Arculeo, 2003; Pipitone & Vaccaro, 2011). Bathymetric range between 2 and 637 m (d'Udekem d'Acoz, 1999). Often holding algae or small pieces of sponges over the carapace with the fifth pair of pereiopods, and sometimes reported below the tentacles of the anemone *Telmatostylis cricoides* (Duchassaing, 1850) (d'Udekem d'Acoz, 1999).

Ovigerous females have been recorded in February (García Raso, 1984) and from April to September (Zariquiey Álvarez, 1968; Manning & Holthuis, 1981).

Our specimens were collected on coarse sand, coarse muddy sand, sandy mud with shell debris and muddy sand bottoms, at depths between 80–98 and 334–352 m. Ovigerous females were captured in November and December.

GEOGRAPHIC DISTRIBUTION

Eastern Atlantic, from the Bay of Biscay to Angola, including the Azores, Madeira, Cape Verde, Desertas, Canary and Gulf of Guinea Islands; the Walter Shoals (E South Africa) (Guinot & Richer de Forges, 1995); Central and Western Mediterranean Basin (d'Udekem d'Acoz, 1999).

Later records for this species (Monteiro *et al.*, 2001; Pipitone & Arculeo, 2003; Ungaro *et al.*, 2005; Henriksen, 2009; Pipitone & Vaccaro, 2011; Muñoz *et al.*, 2012) fit well within this geographic distribution.

REMARKS

The ovigerous females recorded for the first time in November and December indicate that this species spawns all year round except in winter.

MATERIAL EXAMINED

MU14, 502–511 m, (1); MU18, 519–402 m, (4); MU23, 532–415 m, (17); MU37, 403–442 m, (2); MU121, 274–400 m, (1); MU140, 376–377 m, (1); MU150, 292–341 m, (2); MU157, 278–454 m, (1); MU175, 618–850 m, (1); MU188, 627 m, (1); MU263, 615–624 m, (2); MUBV03, 528–538 m, (1); MUBV22, 300 m, (1).

Male: 95.20 mm, female: 76.20 mm, megalopa: 7.78 mm.

IDENTIFICATION

Our specimens agree well with the descriptions and figures provided by Capart (1951: 25) and Zariquey Álvarez (1968: 301).

BIOLOGY

Deep-water species taken on bottoms with mud or sandy mud, over a cold-water coral community (Pipitone & Arculeo, 2003; Isajlović *et al.*, 2009; Capezzuto *et al.*, 2012). The isolated record from the Menez Gwen hydrothermal vent must be considered with caution until confirmed (Martin & Haney, 2005). This species is often reported holding a sponge over the carapace using the fifth pereiopods (Capezzuto *et al.*, 2012) and is also found with cirripeds, gorgonians and sea anemones on carapace and legs (González, 1995; Guinot & Richer de Forges, 1995). Bathymetric range usually between 80 and 300 m (d'Udekem d'Acoz, 1999), although the species was once reported at 10 m (Manning & Holthuis, 1981) and up to 1165 m depth (Cartes *et al.*, 2004). Ovigerous females have been recorded in March, from May to July, October and November (Zariquey Álvarez, 1968; Manning & Holthuis, 1981).

Our specimens were collected in muddy sand and sandy mud bottoms, in depths between 274–400 and 618–850 m. No ovigerous females were caught.

GEOGRAPHIC DISTRIBUTION

North and East Atlantic, from southern Iceland, the Hebrides and southern Scandinavia, south to north-western South Africa (Tripp Seamount), including the Azores, Madeira, Canary and Cape Verde Islands; Mediterranean Sea (d'Udekem d'Acoz, 1999; Martin & Haney, 2005).

Further additional records (Macpherson, 1991; Maynou & Cartes, 2000; Abelló *et al.*, 2002; Biagi *et al.*, 2002; Pipitone & Arculeo, 2003; Sardà *et al.*, 2003; Cartes *et al.*, 2004; Company *et al.*, 2004; Politou *et al.*, 2005; Ungaro *et al.*, 2005; Fanelli *et al.*, 2007; Isajlović *et al.*, 2009; Capezzuto *et al.*, 2012; Muñoz *et al.*, 2012) fall within this geographic range.

Ethusa granulata Norman in Thomson, 1873: 176.

Cymonomus granulatus: Zariquey Álvarez, 1968: 813 (references).

Fig. 3. *Cymonomus granulatus* (Norman, in Thomson, 1873), adult dorsal view, MUBV10.

MATERIAL EXAMINED

MUBV₁₀, 332–344 m, (35).

Males: 4.64–5.23 mm, female: 3.52 mm, ovigerous females: 3.26–3.73 mm.

IDENTIFICATION

Our specimens agree with those described in Milne-Edwards & Bouvier (1900: 34) (see Remarks).

BIOLOGY

Mainly found on shell debris and muddy bottoms (Mura & Cau, 2002), between 155 m (García Raso, 1996) and 2425 m (d'Udekem d'Acoz, 1999). Ovigerous females reported from May to July (García Raso, 1996; Mura & Cau, 2002).

Our specimens were collected at 332–344 m and ovigerous females were captured in November.

GEOGRAPHIC DISTRIBUTION

Eastern Atlantic from SW Scotland to Mauritania; West and Central Mediterranean Sea (d'Udekem d'Acoz, 1999). In the Mediterranean Sea, this species has been reported in the Alborán Sea (Abelló *et al.*, 2002) and in the Sardinian Channel (Mura & Cau, 2002). In the NE Atlantic, Cartes *et al.* (2007) reported the species on Le Danois Bank (Cantabrian Sea).

REMARKS

In our specimens, the mesial margin of the ocular peduncles are more tuberculate than spinulose as described by Milne-Edwards & Bouvier (1900: 34). The rest of the characters agree well with the referred description and, consequently, our specimens remain within this species.

This is the first time that ovigerous females are reported at the end of the year, which suggests a biannual spawning strategy for this species.

Section EURBRACHYURA de Saint Laurent, 1980

Subsection HETEROTREMATA Guinot, 1977

Superfamily CALAPPOIDEA de Haan, 1833

Family CALAPPIDAE de Haan, 1833

Genus *Acanthocarpus* Stimpson, 1871

Acanthocarpus brevispinis Monod, 1946

(Figure 4)

Acanthocarpus bispinosus Milne-Edwards, 1880 var. *brevispinis*, Monod, 1946: 7, figures 1–4, pl. figures 1–2.

Acanthocarpus brevispinis: Manning & Holthuis, 1981: 50 (references).

Fig. 4. *Acanthocarpus brevispinis* Monod, 1946, adult dorsal view, MU51.

MATERIAL EXAMINED

MU51, 468–466 m, (1); MU99, 569–598 m, (1); MU121, 274–400 m, (1); MU134, 311–436 m, (1); MU143, 322 m, (4); MUBV₀₂, 318–330 m, (1); MUBV₁₃, 493–517 m, (3); MUBV₁₄, 300–281 m, (9); MUBV₁₉, 306 m, (12); MUBV₂₂, 300 m, (7).

Males: 15.56–55.29 mm; female: 49.85 mm; ovigerous female: 55.29 mm.

IDENTIFICATION

Our specimens agree well with the descriptions given by Capart (1951: 36; as *Acanthocarpus africanus*) and Manning & Holthuis (1981: 50).

BIOLOGY

Previously reported on sandy and shelly mud bottoms (Manning & Holthuis, 1981), at depths from 100 m (Manning & Holthuis, 1981) to 517 m (Muñoz *et al.*, 2012). Ovigerous females have been recorded in March and October (Manning & Holthuis, 1981).

Our specimens were collected from 274–400 to 569–598 m on sandy mud bottoms; ovigerous females were captured in December.

GEOGRAPHIC DISTRIBUTION

West Africa from Cape Juby (S Morocco) to Namibia (Manning & Holthuis, 1981; Macpherson, 1983, 1991). Further records for this species were reported by Henriksen (2009) from Nigeria and Gabon, and by Muñoz *et al.* (2012) from Guinea-Bissau.

REMARKS

Material from the station MU99 at 569–598 m is the deepest known record for this species; the finding of ovigerous females in December confirms a biannual spawning strategy.

Genus *Calappa* Weber, 1795

Calappa pelii Herklots, 1851

(Figure 5)

Calappa Pelii Herklots, 1851: 12.

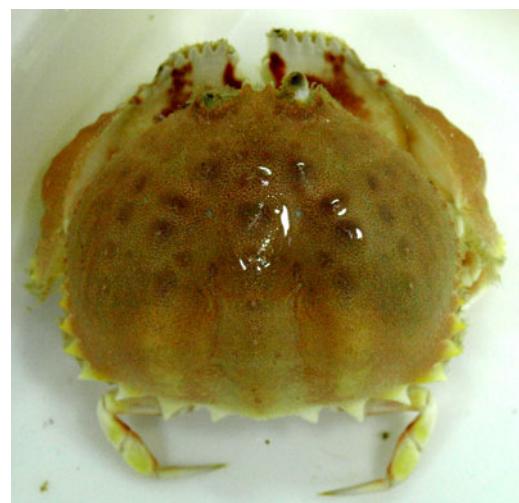

Fig. 5. *Calappa pelii* Herklots, 1851, female CL: 33.94 mm dorsal view, MU158.

MATERIAL EXAMINED

MU158, 80–98 m, (1); MUBV01, 112 m, (4); MUBV15, 148–135 m, (1); MUBV21, 107–109 m, (7).
Males: 21.11–31.91 mm; females: 30.14–40.79 mm; ovigerous female: 58.87 mm.

IDENTIFICATION

Our specimens agree well with the descriptions given by Capart (1951: 39, as *Calappa peli*) and Manning & Holthuis (1981: 52).

BIOLOGY

Bottoms of mud and broken shells, usually at depths between 8–20 and 400 m. Ovigerous females reported in March, May, August, October and December (Manning & Holthuis, 1981).

Our specimens were collected in depths between 80–98 and 135–148 m on sandy bottoms, and ovigerous females were captured in November.

GEOGRAPHIC DISTRIBUTION

West Africa from Western Sahara to Namibia, including Principe Island, and Central Mediterranean Sea (Macpherson, 1991; d'Udekem d'Acoz, 1999). Recent records for this species are from Guinea-Bissau (Muñoz et al., 2012) and from the Gulf of Guinea (Henriksen, 2009).

Superfamily CANCROIDEA Latreille, 1802

Family ATELECYCLIDAE Ortmann, 1893

Genus *Atelecyclus* Leach, 1814

Atelecyclus rotundatus (Oliví, 1792)

Cancer rotundatus Oliví, 1792: 47, pl. 2 figure 2.

Atelecyclus rotundatus: Manning & Holthuis, 1981: 68 (references); González Gurriarán & Méndez, 1986: 113, figure 38, photo 26.

MATERIAL EXAMINED

MUBV10, 332–344 m, (1).

Female: 27.64 mm.

Fig. 6. *Atelecyclus rotundatus* (Oliví, 1792), female CL: 27.64 mm dorsal view, MUBV10.

IDENTIFICATION

Our specimen agrees well with the specifications provided by Forest (1957: 469) and the descriptions in González Gurriarán & Méndez (1986: 113).

BIOLOGY

Recorded from sandy bottoms, often with gravel and small stones as well as muddy sand, shelly sand, gravel with shell debris and mud; also recorded on rocks, coralligenous substrates and in *Posidonia* meadows (d'Udekem d'Acoz, 1999; Pipitone & Arculeo, 2003; Ateş et al., 2006; Guillén et al. 2011). Bathymetric distribution from intertidal to 795 m, usually between 9 and 300 m (d'Udekem d'Acoz, 1999). Ovigerous females were recorded in January and December (García Raso, 1984).

Only one female was collected in the MAURIT surveys between 332–344 m.

GEOGRAPHIC DISTRIBUTION

Eastern Atlantic from SW Faroe Islands to South Africa (beyond Cape of Good Hope, Barnard, 1950), including the Canary, Cape Verde and Ascension Islands; Mediterranean Sea (d'Udekem d'Acoz, 1999).

Later records (Abelló et al., 2002; Pipitone & Arculeo, 2003; Ateş et al., 2006; Serrano et al., 2006, 2011; García-Muñoz et al., 2008; Sánchez et al., 2008; Muñoz et al., 2012; Ellis et al., 2013) fit well within this geographic distribution.

Superfamily DORIPPOIDEA MacLeay, 1838

Family DORIPPIDAE MacLeay, 1838

Genus *Medorippe* Manning & Holthuis, 1981

Medorippe lanata (Linnaeus, 1767)

(Figure 7)

Cancer lanatus Linnaeus, 1767: 1044.

Medorippe lanata: Manning & Holthuis, 1981: 31, figures 4a–h (references).

MATERIAL EXAMINED

MU210, 86–90 m, (1); MUBV01, 112 m, (2); MUBV21, 107–109 m, (19).

Males: 6.88–20.84 mm, female: 11.27 mm, ovigerous female: 23.68 mm.

IDENTIFICATION

Our specimens agree well with the description and figures in Capart (1951: 30; as *Dorippe lanata*) and in Manning & Holthuis (1981: 31).

Fig. 7. *Medorippe lanata* (Linnaeus, 1767), ovigerous female CL: 23.68 mm dorsal view, MUBV01.

BIOLOGY

Mostly recorded on soft heterogeneous substrates (mud, sandy mud, muddy sand and sand) at depths varying from 9 to 769 m (d'Udekem d'Acoz, 1999; El Lakhach *et al.*, 2012). On Mediterranean soft bottoms, this species has been associated with demersal assemblages currently exploited by trawling (Rossetti *et al.*, 2006). Ovigerous females have been reported from March to November (Zariquey Álvarez, 1968: 313 as *Dorippe lanata*; Manning & Holthuis, 1981: 32; Modena *et al.*, 2001; Rossetti *et al.*, 2006).

Our specimens were collected from 86–90 to 112 m, on sand with biogenic debris bottoms. Ovigerous females were captured in November.

GEOGRAPHIC DISTRIBUTION

East Atlantic, from Portugal to South Africa (up to Natal) and Mozambique, including the Canary Islands and Mediterranean Sea (Barnard, 1950, 1955; Manning & Holthuis, 1981; d'Udekem d'Acoz, 1999).

Further records (Modena *et al.*, 2001; Abelló *et al.*, 2002; Biagi *et al.*, 2002; Pipitone & Arculeo, 2003; Ungaro *et al.*, 2005; Rossetti *et al.*, 2006; Fanelli *et al.*, 2007; Henriksen, 2009; El Lakhach *et al.*, 2012; Muñoz *et al.*, 2012) fit well within its geographic distribution.

REMARKS

Manning & Holthuis (1981) erected the genera *Medorippe* and *Phyllodorippe* in order to accommodate the Atlantic species of dorippids previously included in the genus *Dorippe*. *Medorippe* can be differentiated from *Phyllodorippe* by the male gonopod morphology (short, stubby, straight, without distal appendages and lobulated at the outer margin of base vs long, slender, S-shaped, with two short distal appendages and lacking a lobe in the proximal part) and by the presence of a row of spines on the dorsal margin of pereiopods 2 and 3.

Family ETHUSIDAE Guinot, 1977

Genus *Ethusa* Roux, 1830

Ethusa rosacea A. Milne-Edwards & Bouvier, 1897
(Figure 8)

Ethusa rosacea A. Milne-Edwards & Bouvier, 1897: 298; Monod, 1956: 88 (references); Manning & Holthuis, 1981: 38 (references).

Fig. 8. *Ethusa rosacea* A. Milne Edwards & Bouvier, 1897, ovigerous female CL: 11.16 mm dorsal view, MUBV17.

MATERIAL EXAMINED

MUBV17, 1022–1026 m, (1).
Ovigerous female: 11.16 mm.

IDENTIFICATION

Our specimen agrees well with the original description and the figures provided later by Milne-Edwards & Bouvier (1900: pls III figure 5, X figures 5–8) and by Capart (1951: figure 5).

BIOLOGY

Bottoms of sand, muddy sand and sandy mud (Manning & Holthuis, 1981; d'Udekem d'Acoz, 1999), with a bathymetric range of 84 m (Henriksen, 2009) to 1113 m (d'Udekem d'Acoz, 1999). Ovigerous females have been recorded in March, April and June (Manning & Holthuis, 1981).

Only one ovigerous female was collected in December between 1022–1026 m.

GEOGRAPHIC DISTRIBUTION

The species is recorded in the Eastern Atlantic from scattered localities between Mauritania and Angola, including the Canary and Cape Verde Islands (d'Udekem d'Acoz, 1999). Henriksen (2009) reported this species from the Gulf of Guinea.

REMARKS

The poor development of the outer frontal teeth, the sparse setation of the carapace and the transversal broadness of the walking legs dactylus ensure the identification of our specimen as *E. rosacea*.

Ovigerous females are recorded for the first time at the end of the year, suggesting a biannual spawn strategy.

Ethusa rugulosa A. Milne-Edwards & Bouvier, 1897
(Figure 9)

Ethusa rugulosa A. Milne-Edwards & Bouvier, 1897: 297; Manning & Holthuis, 1981: 39 (references).

MATERIAL EXAMINED

MUBV01, 112 m, (1); MUBV02, 318–330 m, (1); MUBV10, 332–344 m, (26); MUBV20, 155 m, (1); MUBV21, 107–109 m, (1).
Males: 8.83–16.60 mm, females: 11.64–14.93 mm, ovigerous females: 11.09–12.64 mm.

Fig. 9. *Ethusa rugulosa* A. Milne-Edwards & Bouvier, 1897, adult male dorsal view, MUBV21.

IDENTIFICATION

Our specimen agrees well with the description and figures of the type provided by Milne-Edwards & Bouvier (1900: 24).

BIOLOGY

This species has been recorded from different soft bottoms, including sand and shells, muddy sand, shelly mud and also hard substrates (Manning & Holthuis, 1981: 39; Henriksen, 2009: 154). Bathymetric range between 55–60 and 275 m (Manning & Holthuis, 1981: 39). Ovigerous females have been recorded in July (Manning & Holthuis, 1981: 39).

Our specimens were collected from 107–109 to 332–344 m with ovigerous females in November.

GEOGRAPHIC DISTRIBUTION

Eastern Atlantic, recorded from scattered localities: Mauritania (present work), the Cape Verde Islands, Senegal, Sierra Leona, Liberia and Angola (Manning & Holthuis, 1981) (see Remarks). This species was also reported from the Gulf of Guinea by Henriksen (2009).

REMARKS

Our finding is the first record of this species in Mauritania, extending the northern distribution up to Cape Blanc. Also, the bathymetric range is extended from 275 m reported in the literature to 332–344 m in this work.

The presence of ovigerous females for the first time at the end of the year suggests a biannual spawn.

Superfamily GONEPLACOIDEA MacLeay, 1838
 Family GONEPLACIDAE MacLeay, 1838
 Genus *Goneplax* Leach, 1814
Goneplax barnardi (Capart, 1951)
 (Figure 10)

Carcinoplax barnardi Capart, 1951: 170, figures 65 a, b.
Goneplax barnardi: Castro, 2007: 689, figure 27b (references).

MATERIAL EXAMINED

MU44, 606–596 m, (1); MU54, 414–451 m, (2); MU57, 430–406 m, (5); MU123, 278–362 m, (1); MU152, 381–316 m, (1); MU214, 650–588 m, (1); MU216, 422 m, (5); MUBV03, 528–538 m, (6); MUBV09, 549–555 m, (1); MUBV13, 493–517 m, (14); MUBV14, 300–281 m, (7); MUBV18, 559–574 m, (11); MUBV19, 306 m, (1); MUBV25, 499–520 m, (2).
 Males: 9.73–20.01 mm, females: 12.52–15.61 mm, ovigerous females: 11.18–15.51 mm.

Fig. 10. *Goneplax barnardi* (Capart, 1951), male CL: 20.01 mm dorsal view, MUBV09.

IDENTIFICATION

Our specimens agree well with the description of the type and with the detailed figures provided in Monod (1956: 351).

BIOLOGY

Previously reported from mud and sandy mud bottoms, from 200 to 590 m (d'Udekem d'Acoz, 1999: 241). Ovigerous females have been recorded in March and May (Manning & Holthuis, 1981: 160).

Our specimens were collected between 278–362 and 588–650 m on sand and sandy mud bottoms. Ovigerous females were captured in December.

GEOGRAPHIC DISTRIBUTION

East Atlantic, from Western Sahara to Angola, including the Cape Verde Islands (Castro, 2007) (see Remarks). Muñoz et al. (2012) later reported this species from Guinea-Bissau.

REMARKS

Castro (2007) removed this species from the former *Carcinoplax* to *Goneplax* because of its longer eye peduncles, dorsal margin of the ambulatory legs (P2–P5) meri armed with an acute distal tooth (although this character is also present in the Western Pacific *Carcinoplax spinosissima* Rathbun, 1914), and slender dactyli carinated on both sides. Obviously, Castro (2007: 690) meant Eastern Atlantic when he wrote 'Western Atlantic along the west coast of Africa'.

This record constitutes the first for the species in Mauritanian waters and it is the first time that ovigerous females are reported at the end of the year. The known spawn period (March, May and December) suggests that the species is a biannual spawner.

Goneplax rhombooides (Linnaeus, 1758)
 (Figure 11)

Cancer rhombooides Linnaeus, 1758: 626.
Goneplax rhombooides: Castro, 2007: 687, figure 27A (references).

MATERIAL EXAMINED

MU143, 322 m, (1); MU207, 88–117 m, (1); MU227, 183–181 m, (3); MUBV14, 300–281 m, (2).
 Males: 9.98–13.06 mm, ovigerous female: 10.05 mm.

Fig. 11. *Goneplax rhombooides* (Linnaeus, 1758), male CL: 13.06 mm dorsal view, MU143.

IDENTIFICATION

Our specimens agree well with the descriptions and figures in Monod (1956: 354; as *Goneplax angulata*) and in Zariquey Álvarez (1968: 414).

BIOLOGY

Burrowing species (Atkinson, 1974; Neudecker *et al.*, 2011), usually found in mud, sandy mud, muddy sand and sand bottoms; also on rocks and shells (Manning & Holthuis, 1981; d'Udekem d'Acoz, 1999; Pipitone & Arculeo, 2003; Ateş *et al.*, 2006; Trenkel *et al.*, 2007; Mutlu & Ergev, 2008; Fanelli *et al.*, 2009; Metin *et al.*, 2009; Guillén *et al.*, 2011; Neudecker *et al.*, 2011; El Lakhach *et al.*, 2012; Ellis *et al.*, 2013). Bathymetric range from intertidal zone (d'Udekem d'Acoz, 1999) to 600–999 m (Company *et al.*, 2004; Cartes *et al.*, 2009). Ovigerous females were reported from January to March, from May to August, and in November and December (Zariquey Álvarez, 1968; Manning & Holthuis, 1981; García Raso, 1984, 1996).

Our specimens were collected between 88–117 and 322 m on sandy mud and muddy sand bottoms; and the ovigerous female was captured in December.

GEOGRAPHIC DISTRIBUTION

East Atlantic, from the coast of SE Norway and SW Sweden, the North Sea, SW United Kingdom and Ireland, the continental European coast southwards to Western Africa, at least up to Senegal (see Remarks), including Madeira and the Canary Islands, and in the Mediterranean Sea (Castro, 2007; Guinot & Castro, 2007; Berggren, 2008; Berggren & Stefan, 2010).

Further records for this species from European waters and in the Mediterranean Sea, not included in the above-mentioned references, are Maynou & Cartes (2000), Monteiro *et al.* (2001), Biagi *et al.* (2002), Pipitone & Arculeo (2003), Company *et al.* (2004), Ungaro *et al.* (2005); Vincent (2005), Ateş *et al.* (2006), Sartor *et al.* (2006), Serrano *et al.* (2006), Fanelli *et al.* (2007), Trenkel *et al.* (2007), Mutlu & Ergev (2008), Cartes *et al.* (2009), Fanelli *et al.* (2009), Metin *et al.* (2009), Neudecker *et al.* (2011), Serrano *et al.* (2011), El Lakhach *et al.* (2012) and Ellis *et al.* (2013).

REMARKS

Goneplax rhomboides has long been described as a species with a wide geographic distribution in East Atlantic waters, from the North Atlantic to South Africa (Barnard, 1950; Manning & Holthuis, 1981; d'Udekem d'Acoz, 1999). However, Guinot & Castro (2007) described the new species, *Goneplax clevai*, from the South Atlantic and western limits of the Indo-West Pacific region, including in their new species some specimens reported from the Ivory Coast to South Africa and previously identified as *G. rhomboides*. Guinot & Castro (2007: 25) accept as valid the material from Senegal mentioned by Monod (1956) for *G. rhomboides*. Consequently, the southern distribution limit of *G. rhomboides* will remain unclear southwards from Senegal until all the recorded specimens from the West African coasts can be properly checked.

Superfamily LEUCOSIOIDEA Samouelle, 1819

Family LEUCOSIIDAE Samouelle, 1819

Genus *Ebalia* Leach, 1817

Fig. 12. *Ebalia nux* Norman in A. Milne-Edwards, 1883, male CL: 7.02 mm dorsal view, MUBV10.

Ebalia nux Norman in A. Milne-Edwards, 1883

(Figure 12)

Ebalia nux A. Milne-Edwards, 1883: pl. 5; Holthuis & Manning, 1981: 61 (references).

MATERIAL EXAMINED

MU87, 271–305 m, (1); MUBV10, 332–344 m, (3).

Males: 7.02–7.20 mm.

IDENTIFICATION

Our specimens agree well with those figured by Milne-Edwards & Bouvier (1900: plates III, figure 7, XIII: figures 1–5), and with the descriptions provided by Zariquey Álvarez (1968: 328), and by González Gurriarán & Méndez (1986: 71).

BIOLOGY

This species has been recorded on shell, sand, sand and rocks, sand with calcareous algae, mud and sandy mud bottoms (d'Udekem d'Acoz, 1999; Ateş *et al.*, 2006); it has been also reported living on the sea pen, *Pteroeides spinosum* (Ellis, 1764), in the Mediterranean Sea (Porporato *et al.*, 2012). Depths records vary between 80 and 2983 m but usually from 150 to 500 m (d'Udekem d'Acoz, 1999). Ovigerous females have been recorded in March (Manning & Holthuis, 1981) and May–June (García Raso, 1996).

Our specimens, all males, were collected between 271–305 and 332–344 m.

GEOGRAPHIC DISTRIBUTION

Eastern Atlantic, from the Shetland Islands and Norway to Mauritania, including the Azores, Canary and Cape Verde Islands; and Mediterranean Sea (d'Udekem d'Acoz, 1999).

Later records for this species (Abelló *et al.*, 2002; Ateş *et al.*, 2006; Porporato *et al.*, 2012) are all from the Mediterranean, with the exception of a report by Cartes *et al.* (2007) from Le Danois Bank (Cantabrian Sea).

Genus *Pseudomyra* Capart, 1951

Pseudomyra mbizi Capart, 1951

(Figure 13)

Pseudomyra mbizi Capart, 1951: 49, figure 14, pl. II figure 24; Manning & Holthuis, 1981: 66 (references).

MATERIAL EXAMINED

MUBV01, 112 m, (9); MUBV15, 148–135 m, (93).

Fig. 13. *Pseudomyra mbizi* Capart, 1951, adult dorsal view, MUBV01.

Males: 16.54–20.31 mm, female: 15.96–17.45 mm, ovigerous females: 15.45–17.63 mm.

IDENTIFICATION

Our specimens agree well with the original description and figures.

BIOLOGY

The species has been collected on a variety of bottoms, such as mud, sandy mud with shells, mud with foraminifera, muddy sand, broken shells, and also on coral and rocks. Bathymetric range between 12–15 and 300 m, although usually recorded from 50 to 100 m (Manning & Holthuis, 1981). Ovigerous females have been recorded from March to August, October and December (Manning & Holthuis, 1981).

Our specimens were captured in depths between 112 and 135–148 m. The ovigerous females were caught in December.

GEOGRAPHIC DISTRIBUTION

West Africa from Mauritania (present work) to Angola (Manning & Holthuis, 1981) (see Remarks). Henriksen (2009) reports this species from the Gulf of Guinea.

REMARKS

This is the first record of this species from Mauritanian waters, which extends its north distribution up to the Banc d'Arguin.

Superfamily MAJOIDEA Samouelle, 1819

Family EPIALTIDAE MacLeay, 1838

Genus *Pisa* Leach, 1814

Pisa armata (Latreille, 1803)

(Figure 14)

Maja armata Latreille, 1803: 98.

Pisa armata: Manning & Holthuis, 1981: 318 (references).

MATERIAL EXAMINED

MU120, 109–105 m, (1); MU131, 102–104 m, (2); MU136, 103–112 m, (1); MU139, 96–97 m, (2); MU147, 134–139 m, (1); MU154, 92–102 m, (2); MU211, 92–109 m, (1); MU261, 111–146 m, (1); MUBV15, 148–153 m (1).

Males: 17.74–22.14 mm, females: 21.08–22.12 mm, ovigerous females: 22.27–24.67 mm.

Fig. 14. *Pisa armata* (Latreille, 1803), female CL: 22.12 mm dorsal view, MU139.

IDENTIFICATION

Our specimens agree well with the descriptions and figures provided by Capart (1951: 90) and by González-Gurriarán & Méndez (1986: 183).

BIOLOGY

This species has been recorded from rocky bottoms with gorgonians and corals, and also from sandy mud, mud, sand and shells bottoms (Manning & Holthuis, 1981; d'Udekem d'Acoz, 1999; García Raso & Manjón-Cabeza, 2002; Pipitone & Arculeo, 2003; Ateş et al., 2006). Pipitone & Arculeo (2003) recorded the species on bottoms with *Posidonia* meadows, although they showed no correlation with the meadow structure (Sánchez-Jerez et al., 2000). Bathymetric range extends from 3–10 m (Pipitone & Arculeo, 2003) to 162 m (d'Udekem d'Acoz, 1999). Ovigerous females were recorded from March to May, from July to August and from November to December (Zariquey Álvarez, 1968; Manning & Holthuis, 1981; García Raso, 1984).

Our specimens, often with sponges, ascidians and bryozoans over the carapace, were captured between 96–97 and 135–148 m on shell debris, sand and sandy mud bottoms. Ovigerous females were collected in December.

GEOGRAPHIC DISTRIBUTION

East Atlantic from Southern North Sea and SW British Isles to Angola, including the Azores, Canary and Cape Verde Islands; and Mediterranean Basin (d'Udekem d'Acoz, 1999).

Later records for this species (Sánchez-Jerez et al., 2000; Abelló et al., 2002; García Raso & Manjón-Cabeza, 2002; Pipitone & Arculeo, 2003; Ateş et al., 2006) fit well within its distribution.

REMARKS

Ng et al. (2008) reviewed the nomenclatural and taxonomic problems within brachyurans, and rearranged the former family Pisididae as a subfamily into Epialtidae.

Family INACHIDAE MacLeay, 1838
Inachus Weber, 1795
Inachus aguiarii de Brito Capello, 1876
 (Figure 15A, B)

Inachus aguiarii de Brito Capello, 1876: 265, pl. 2 figures 1–3
Inachus aguiarii: Manning & Holthuis, 1981: 283 (references).

MATERIAL EXAMINED

MU120, 109–105 m, (4); MU129, 95–93 m, (1); MU131, 102–104 m, (1); MU226, 109–107 m, (1); MU277, 112–110 m, (1).

Males: 9.35–11.61 mm, ovigerous females: 10.35–11.36 mm.

IDENTIFICATION

Our specimens agree with those described in Zariquey Álvarez (1948: 301 as *Inachus thoracicus* ssp. *aguiarii*).

BIOLOGY

Previously recorded from hard bottoms with sponges and kelp; also from soft bottoms of sandy mud often mixed with shell fragments, sand or sand with calcareous algae. Recorded at depths from 20 to 100 m (d'Udekem d'Acoz, 1999). Ovigerous females recorded in February, March and August (Zariquey Álvarez, 1968; García Raso, 1989).

Our specimens were collected from 93–95 to 110–112 m on sand, coarse sand, gravel and sandy mud bottoms.

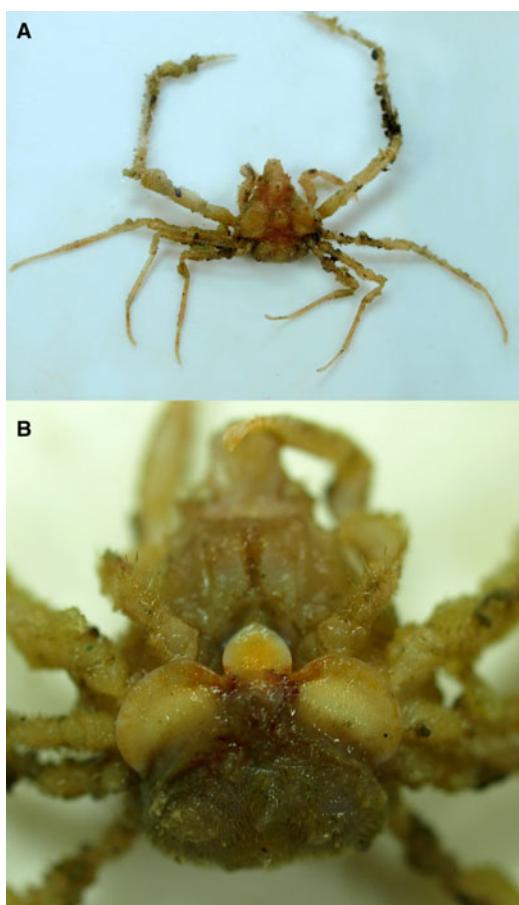

Fig. 15. *Inachus aguiarii* Brito Capello, 1876, ovigerous female CL: 11.36 mm, MU277: (A) general dorsal view; (B) ventral view, detail of sternal callosities.

Ovigerous females were captured in November and December.

GEOGRAPHIC DISTRIBUTION

East Atlantic from Portugal to Guinea including the Desertas and Canary Islands (d'Udekem d'Acoz, 1999); in the Mediterranean Sea, the species was reported only in the Alboran and Aegean Seas (Guerao & Abelló, 2007).

REMARKS

Bathymetric range is slightly increasing from that reported in the literature.

Our records of ovigerous females in November and December suggests that this species spawns all year round.

Inachus angolensis Capart, 1951
 (Figure 16)

Inachus angolensis Capart, 1951: 72, figure 72, pl. I figure 7, pl. II figure 10; Manning & Holthuis, 1981: 283 (references).

MATERIAL EXAMINED

MU88, 94–120 m, (1); MU130, 252–362 m, (1); MU133, 87 m, (1); MU137, 81–84 m, (3); MU161, 89–92 m, (1); MU168, 87–92 m, (1); MU174, 85–84 m, (4); MU205, 89–93 m, (1); MU210, 86–90 m, (9); MU212, 163–200 m, (1); MU251, 107 m, (1); MU260, 101–120 m, (1); MU291, 106–137 m, (1); MUBV01, 112 m, (12); MUBV02, 318–330 m, (1); MUBV14, 300–281 m, (1); MUBV15, 148–135 m, (11); MUBV21, 107–109 m, (6).

Males: 10.04–15.11 mm, females: 8.36–13.67 mm, ovigerous females: 11.56–15.35 mm.

IDENTIFICATION

Our specimens agree well with the original description and also with the notes and the figures provided by Monod (1956: 524, figures 712 and 713).

BIOLOGY

This species has been recorded from mud, sandy mud and sandy bottoms (Manning & Holthuis, 1981), at depths from 0–81 m (Henriksen, 2009) up to at least 350 m (Manning & Holthuis, 1981). Ovigerous females were recorded from February to June, September and October (Manning & Holthuis, 1981).

Our specimens were captured between 81–84 and 252–362 m on coarse sand, sandy mud with gravel or shell

Fig. 16. *Inachus angolensis* Capart, 1951, adult dorsal view, MUBV01.

fragments. Ovigerous females were collected in November and December.

GEOGRAPHIC DISTRIBUTION

West Africa from Western Sahara (Manning & Holthuis, 1981) to Namibia (Macpherson, 1991). Henriksen (2009) reports this species from the Gulf of Guinea.

REMARKS

Our finding of ovigerous females in November and December suggests that this species spawns throughout the year.

Inachus grallator Manning & Holthuis, 1981
(Figure 17A, B)

Inachus grallator Manning & Holthuis, 1981: 287, figures 73, 74.

MATERIAL EXAMINED

MUBV10, 332–344 m, (1); MUBV14, 300–281 m, (1).
Males: 6.91 and 7.72 mm.

IDENTIFICATION

Our specimens agree well with the original description.

BIOLOGY

Reported from green mud, brown sandy mud, muddy sand and green muddy sand, at depths between 100 and 250–300 m (Manning & Holthuis, 1981) and down to 325 m (Fransen, 1991). Ovigerous females have been recorded in January and November (Manning & Holthuis, 1981).

Only two males were collected during the MAURIT surveys, at 281–300 and 332–344 m depth.

GEOGRAPHIC DISTRIBUTION

West Africa in Mauritania (Fransen, 1991 in part; present work) and from Nigeria to Namibia (Manning & Holthuis, 1981; Macpherson, 1991) (see Remarks).

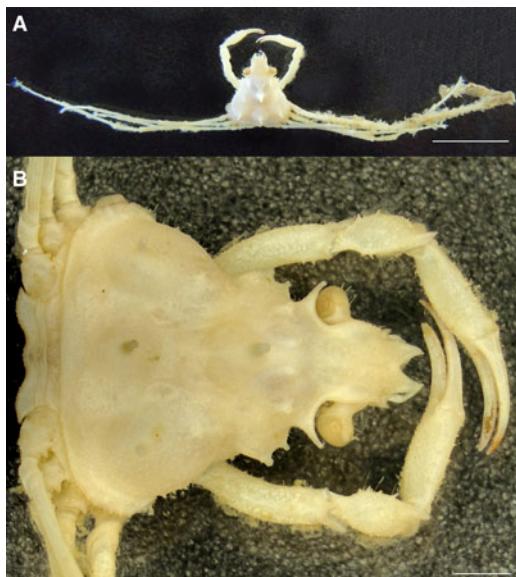

Fig. 17. *Inachus grallator* Manning & Holthuis, 1981, male CL: 6.91 mm, MUBV10, in ethanol: (A) general dorsal view; (B) dorsal carapace detail. Scale bars: (A) 1 cm; (B) 1 mm.

REMARKS

Although the possibility of finding this species up to the Western Sahara (Manning & Holthuis, 1981) or the Canary Islands (González Pérez & Quiles Lucas, 2003) has been mentioned in the literature, to date no records further north than Nigeria – excepting those in Fransen (1991) – have been reported from Mauritania and the Canary Islands. The fact that Manning & Holthuis (1981) described *I. grallator* as a ‘deep-water species, known to occur at depths between 100 and 250–300 m’ suggests that further revision is required for Fransen’s (1991) records for this species at less than 100 m depth. Our record confirms the presence of this species in Mauritanian waters and slightly increases the previously reported bathymetric range.

This species closely resembles another *Inachus* species, *I. dorsettensis*. However, after analysing some specimens of *I. dorsettensis* from Galicia (NW Spain), we conclude that the slenderness of the pereiopods and the shape of the dactyli of the fifth pereiopods ensure the identification of the Mauritanian material as *I. grallator*.

Inachus leptochirus Leach, 1817
(Figure 18A–C)

Inachus leptochirus Leach, 1817, in Leach 1815–1875: 1 p, pl. XXII.b figures 1, 2, 3; Manning & Holthuis, 1981: 291 (references).

MATERIAL EXAMINED

MU200, 352–334 m, (4); MU204, 155–145 m, (1); MUBV10, 332–344 m, (29).
Males: 9.28–19.21 mm, female: 13.93–19.33 mm, ovigerous females: 10.56–18.37 mm.

IDENTIFICATION

Our specimens agree well with notes and figures in Bouvier (1940: 356) and Zariquey Álvarez (1968: 472).

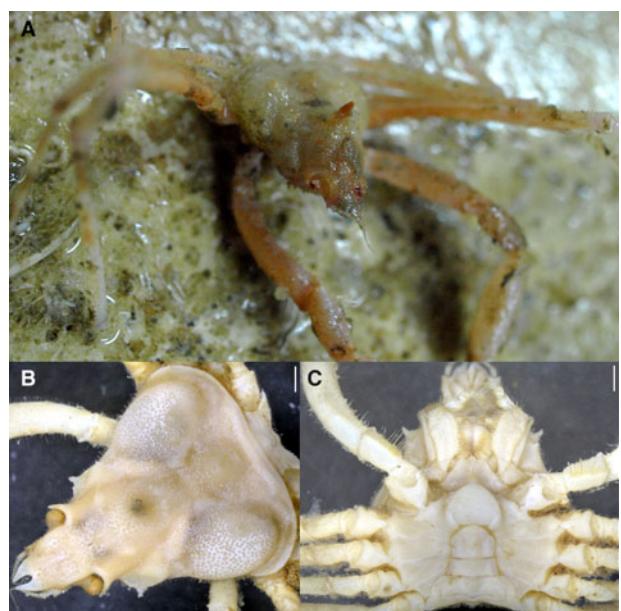

Fig. 18. *Inachus leptochirus* Leach, 1817, MUBV10: (A) adult general view; (B) male CL: 12.42 mm, in alcohol, carapace dorsal view; (C) same ventral view. Scale bars: B, C, 1 mm.

BIOLOGY

Bottoms of gravel, sand, mud and maeal beds, at depths between 27 m (d'Udekem d'Acoz, 1999) and 500–650 m (Serrano *et al.*, 2011). Ovigerous females have been observed in February, May and November (Zariquiey Álvarez, 1968).

Our specimens were captured between 145–155 and 334–352 m on coarse sand and muddy sand bottoms, mixed with shell debris. Ovigerous females were collected in November.

GEOGRAPHIC DISTRIBUTION

East Atlantic, from the Faroe Islands to Mauritania, including the Azores; and Mediterranean Sea (d'Udekem d'Acoz, 1999). This species was recently reported in the N Iberian Peninsula by Serrano *et al.* (2011).

Inachus nanus Manning & Holthuis, 1981
(Figure 19)

Inachus nanus Manning & Holthuis, 1981: 291, figure 75a–e.

MATERIAL EXAMINED

MU166, 87–85 m, (2); MU207, 88–117 m, (1); MU212, 163–200 m, (1); MU261, 111–146 m, (1).
Male: 9.50 mm, ovigerous female: 6.72 mm.

IDENTIFICATION

Our specimens agree well with the original description.

BIOLOGY

Previously reported on broken shells, bryozoans, gravel, mud with foraminifera and muddy sand bottoms. Depth records between 29 and 118 m (d'Udekem d'Acoz, 1999: 198). Ovigerous females have been collected in February, May to July, September and October (Manning & Holthuis, 1981).

Our specimens were found between 85–87 and 163–200 m on muddy sand, coarse muddy sand and shell debris bottoms. Ovigerous females were captured in December.

GEOGRAPHIC DISTRIBUTION

West Africa from Mauritania to Cameroon, including the Canary Islands (d'Udekem d'Acoz, 1999).

Fig. 19. *Inachus nanus* Manning & Holthuis, 1981, ovigerous female CL: 6.72 mm, MU166, in ethanol, dorsal view. Scale bar 1 mm.

REMARKS

This record slightly increases the bathymetric range of this species down to 163–200 m; the presence of ovigerous females in December suggests that this species spawns throughout the year.

Genus *Macropodia* Leach, 1814
Macropodia gilsoni (Capart, 1951)
(Figure 20A, B)

Achaeopsis gilsoni Capart 1951: 65, pl. I figure 4, 10, pl. II figure 3.

Macropodia gilsoni: Manning & Holthuis, 1981: 297 (references).

MATERIAL EXAMINED

MU119, 82–80 m, (2); MU120, 109–105 m, (3); MU131, 102–104 m, (1); MU138, 123–130 m, (2); MU139, 96–97 m, (1); MU149, 93–146 m, (1); MU151, 110–134 m, (1); MU156, 107–102 m, (1); MU161, 89–92 m, (2); MU166, 87–85 m, (2); MU168, 87–92 m, (2); MU170, 102–92 m, (13); MU210, 86–90 m, (4); MU217, 111–113 m, (1); MU223, 116–117 m, (2); MU233, 165–189 m, (1); MU235, 123 m, (1); MUBV15, 148–135 m, (10); MUBV21, 107–109 m, (1).

Males: 4.71–9.36 mm, females: 3.21–5.09 mm, ovigerous females: 11.05–4.35 mm.

Fig. 20. *Macropodia gilsoni* (Capart, 1951), ovigerous female CL: 14.35 mm, MUBV21: (A) general dorsal view; (B) dorsal carapace detail.

IDENTIFICATION

Our specimens agree well with the description of the type and also with the figures provided by Monod (1956: 555).

BIOLOGY

Species recorded on various kinds of muddy bottoms, including bottoms with shells and bryozoans or foliate foraminifera (Manning & Holthuis, 1981), at depths from 37 m (Holthuis & Manning, 1981) up to 264 m (Henriksen, 2009, see Remarks). Ovigerous females recorded throughout the year, except in July (Manning & Holthuis, 1981: 297).

Our specimens were captured between 80–82 and 165–189 m on sandy mud, sand and muddy sand bottoms usually mixed with shell debris. Some specimens carried the hydrozoan *Obelia bidentata* Clark, 1875, on the carapace and legs. Ovigerous females were collected in November and December.

GEOGRAPHIC DISTRIBUTION

West Africa from Mauritania (present work) to Angola (Manning & Holthuis, 1981) (see Remarks). Henriksen (2009) reported this species off Nigeria, Cameroon and Congo.

REMARKS

Our record is the first report of this species in Mauritania, extending its geographic distribution northwards from Senegal to the Banc d'Arguin.

The record for this species in Henriksen (2009) from Cameroon at station 938, Long.: 9.150 Lat.: 3.900, at 0 m depth, must be considered as an error (0 m, null sampling?).

Macropodia hesperia Manning & Holthuis, 1981
(Figure 21)

Macropodia hesperia Manning & Holthuis, 1981: 298, figure 77a–e.

MATERIAL EXAMINED

MU119, 82–80 m, (1); MU129, 95–93 m, (1); MU154, 92–102 m, (2).

Male: 6.48 mm, female: 6.52 mm, ovigerous female: 5.82 mm.

IDENTIFICATION

Our specimens agree well with the original description.

Fig. 21. *Macropodia hesperia* Manning & Holthuis, 1981, male CL: 6.48 mm, MU119, in ethanol, dorsal view. Scale bar 1 mm.

BIOLOGY

Previously recorded on bottoms of mud, sand and compacted sand, at depths varying from 46–49 to 82–97 m. Ovigerous females have been reported in May (Manning & Holthuis, 1981).

Our specimens were captured between 80–82 and 92–102 m on compact coarse sand bottoms.

Some specimens carried the hydrozoan species *Nemertesia* sp. and some colonies of the branched bryozoan species *Synnotum aegyptiacum* (Audouin, 1826) on their carapaces. The only ovigerous female was collected in December.

GEOGRAPHIC DISTRIBUTION

West Africa from Mauritania (present work) to Nigeria (Manning & Holthuis, 1981).

REMARKS

González Pérez (1995) mentioned one specimen from the Canary Islands identified as *Macropodia* aff. *hesperia* and collected at 821 m. However, since all the previous records of this species, including those in this study, were found in depths between 46–49 and 92–102 m, we don't consider as valid the record from Canary Islands until further confirmation of the species identification.

Our finding extends the distribution area of this species northwards, from Senegal up to Cape Timiris.

The record of ovigerous females in December indicates that this species spawns at least biannually.

Macropodia longipes (A. Milne-Edwards & Bouvier, 1899)
(Figure 22)

Stenorhynchus longipes A. Milne-Edwards & Bouvier, 1899: 48
Macropodia longipes: Manning & Holthuis, 1981: 300
(references).

MATERIAL EXAMINED

MU277, 112–110 m, (1).

Male: 7.45 mm.

IDENTIFICATION

Our specimen agrees well with descriptions provided in Forest & Zariquey Álvarez (1964: 226) and González-Gurriarán & Méndez (1986: 169).

Fig. 22. *Macropodia longipes* (A. Milne-Edwards and Bouvier, 1899), male CL: 7.45 mm MU277, dorsal view. Scale bar: 1 mm.

BIOLOGY

Species reported in the literature from bottoms of sand and broken shells (Anadon, 1981), sand, silt, gravel and coarse sands (Serrano *et al.*, 2011), and in seagrasses (Ateş *et al.*, 2006). Depth records from 9 m (d'Udekem d'Acoz, 1999) to 1249 m (Cartes *et al.*, 2004). Ovigerous females recorded in February, March, August and September (Zariquey Álvarez, 1968; Pipitone & Tumbiolo, 1993: 362).

The only specimen examined here was a male, collected between 110 and 112 m on a muddy sand bottom.

GEOGRAPHIC DISTRIBUTION

East Atlantic, from the Gulf of Gascogne to Mauritania, including the Cape Verde Islands; and Mediterranean Sea (Forest, 1978 as *Macropodia tenuirostris longipes*).

Further records for this species all refer to the Mediterranean Sea (Modena *et al.*, 2001; Abelló *et al.*, 2002; Biagi *et al.*, 2002; Cartes *et al.*, 2004; Colloca *et al.*, 2004; Politou *et al.*, 2005; Ungaro *et al.*, 2005; Ateş *et al.*, 2006; Fanelli *et al.*, 2007; García-Muñoz *et al.*, 2008; Serrano *et al.*, 2011).

REMARKS

Since Forest (1978) declared *Macropodia tenuirostris longipes* as the deepest form of *M. tenuirostris tenuirostris*, some authors subsequently synonymized both subspecies under the name *Macropodia tenuirostris* (d'Udekem d'Acoz, 1999; Pipitone & Arculeo, 2003). However, we follow Ng *et al.*

(2008), who kept them as two different species, only including here references that refer to *M. longipes* as a separate species or subspecies.

Although the rostrum of our specimen is a little damaged, the slightly curved (not arcuated) P4, P5 dactylus, the basal article of antenna with strong spines ventrally, the presence of a nuchal spine and the absence of spines on the supraorbital margin ensure its identification as *M. longipes*.

Macropodia macrocheles (A. Milne-Edwards & Bouvier, 1898) (Figure 23A–C)

Stenorhynchus macrocheles A. Milne-Edwards & Bouvier, 1898: 153

Macropodia macrocheles: Manning & Holthuis, 1981: 301 (references)

MATERIAL EXAMINED

MU100, 236–238 m, (3); MU105, 343–346 m, (1); MU141, 280–277 m, (11); MU149, 93–146 m, (1); MU155, 210–257 m, (3); MU157, 278–454 m, (3); MU159, 224–229 m, (7); MU173, 314–540 m, (1); MU179, 303–304 m, (1); MU184, 213–202 m, (2); MU233, 165–189 m, (1); MU280, 230–239 m, (2); MUBV22, 300 m, (1).

Males: 4.41–9.75 mm, ovigerous females: 5.17–6.45 mm.

IDENTIFICATION

Our specimens agree well with the descriptions and figures in Milne-Edwards & Bouvier (1900: 159) and Capart (1951: 77).

Fig. 23. *Macropodia macrocheles* (A. Milne-Edwards & Bouvier, 1898): (A) male CL: 8.86 mm dorsal view, MU184; (B) ovigerous female CL: 5.17 mm, MU141, in ethanol, dorsal view; (C) same, epistome detail. Scale bars B, C: 1 mm.

BIOLOGY

Collected on mud, sand and muddy sand bottoms, at depths between 96 and 300 m (Manning & Holthuis, 1981). Ovigerous females have been recorded in January, February, May, June and December (Manning & Holthuis, 1981).

Our specimens were captured in depths between 93–143 and 314–540 m on muddy sand and sandy mud bottoms. Some specimens carried hydroid colonies of *Clytia gracilis* (Sars, 1850), *Clytia paulensis* (Vanhöffen, 1910), *Antennella secundaria* (Gmelin, 1791) and a branched unidentified bryozoan species of the genus *Bugula* Oken, 1815, on their carapaces. Ovigerous females were collected in December.

GEOGRAPHIC DISTRIBUTION

West Africa, from Mauritania (Manning & Holthuis, 1981) to Namibia (Macpherson, 1991).

REMARKS

Our findings slightly extend the bathymetric range previously reported in the literature.

Family MAJIDAE Samouelle, 1819

Genus *Eurynome* Leach, 1814

Eurynome aspera (Pennant, 1777)
(Figure 24)

Cancer Asper Pennant, 1777: 7, pl IX.A, figure 20.
Eurynome aspera: Griffin, 1974; Manning & Holthuis, 1981: 311 (references).

MATERIAL EXAMINED

MU183, 138–177 m, (1), MU209, 115–150 m, (1).
Males: 10.35–11.87 mm.

IDENTIFICATION

Our specimens agree with the description and figures provided by Zariquiey Álvarez (1968: 462) and González-Gurriarán & Méndez (1986: 178).

BIOLOGY

Mainly reported on firm substrates of relatively large particles, bottoms of shelly sand, calcareous algae, muddy shells and gravel, maerl beds and on rock (Manning & Holthuis, 1981; Ballesteros, 2006) and in *Posidonia* meadows (Pipitone &

Arculeo, 2003; Ateş et al., 2006). Bathymetric range between 10 and 1216 m (d'Udekem d'Acoz, 1999: 188). Ovigerous females reported in April (Zariquiey Álvarez, 1968).

Specimens examined were two males collected at 115–150 and 138–177 m.

GEOGRAPHIC DISTRIBUTION

East Atlantic, from Norway to Angola, including the Azores, Desertas, Canary and Cape Verde Islands; Mediterranean Sea; West Indian Ocean from False Bay, South Africa, to Durban (Griffin, 1974; d'Udekem d'Acoz, 1999).

Later records for this species (Abelló et al., 2002; García Raso & Manjón-Cabeza, 2002; Pipitone & Arculeo, 2003; Ateş et al., 2006; Serrano et al., 2006; Cartes et al., 2007; García-Muñoz et al., 2008; Ellis et al., 2013) fit well within its geographic distribution.

Superfamily PARTHENOPOIDEA MacLeay, 1838

Family PARTHENOPIDAE MacLeay, 1838

Genus *Distolambrus* Tan & Ng, 2007

Distolambrus maltzami (Miers, 1881)

(Figure 25)

Heterocrypta Maltzami Miers, 1881: 209, pl. 13: figure 1

Heterocrypta maltzami: Manning & Holthuis 1981: 322 (references)

Distolambrus maltzami: Tan & Ng, 2007: 103, figure 5; Henriksen, 2009: 80, figure 40

MATERIAL EXAMINED

MUBV21, 107–109 m, (2).

Ovigerous female: 8.08 mm.

IDENTIFICATION

Our specimen agrees well with the description provided by Milne-Edwards & Bouvier (1900: 121, as *Heterocrypta Maltzani* and *Heterocrypta Maltzani* var. *Marioni*).

BIOLOGY

Previously reported from bottoms of shell debris, shelly sand, sand, muddy sand, mud, calcareous algae and rock (Manning & Holthuis, 1981, as *Heterocrypta maltzami*; d'Udekem d'Acoz, 1999, as *Heterocrypta maltzami marionis*). Bathymetric range oscillates between 22 and 550 m (d'Udekem d'Acoz, 1999, as *Heterocrypta maltzami marionis*), but all previous West

Fig. 24. *Eurynome aspera* (Pennant, 1777), male CL: 10.35 mm dorsal view, MU209.

Fig. 25. *Distolambrus maltzami* (Miers, 1881), ovigerous female CL: 8.08 mm, MUBV21, in ethanol, dorsal view. Scale bar: 1 mm.

African records are from less than 100 m depth (0–70 m) (Manning & Holthuis, 1981; as *Heterocrypta maltzami*).

On the West African coast, ovigerous females have been found throughout the year (Zariquiey Álvarez, 1968; as *Heterocrypta maltzami*).

Only one ovigerous female was collected in December during the MAURIT surveys, between 107 and 109 m.

GEOGRAPHIC DISTRIBUTION

Eastern Atlantic Ocean from the Bay of Biscay to Angola, including the Azores and Cape Verde Islands (Manning & Holthuis, 1981), as well as in the Mediterranean Sea (d'Udekem d'Acoz, 1999).

Later records (Pipitone & Arculeo, 2003; Serrano *et al.*, 2006; Henriksen, 2009; Massi *et al.*, 2010) fit well within its geographic distribution.

REMARKS

In their systematic revision of the subfamily Parthenopinae, Tan & Ng (2007) relocated the former *Heterocrypta maltzami* in their new genus *Distolambrus*. Both genera can be easily differentiated by the presence of a V-shaped ridge on the gastric region of *Distolambrus* (U-shaped in *Heterocrypta*); the branchial ridge not continuous with the gastric ridge (continuous in *Heterocrypta*); male with fused thoracic sternites without a transverse groove (with a broad transverse groove in *Heterocrypta*); third maxilliped merus subtriangular (subquadrate in *Heterocrypta*); and the posterior margin not produced beyond the base of the abdomen (produced in *Heterocrypta*).

Genus *Solenolambrus* Stimpson, 1871

Solenolambrus noordendei (Capart, 1951)
(Figure 26)

Heterocrypta noordendei Capart, 1951: 108, figure 37, pl. II figure 15.

Solenolambrus noordendei: Manning & Holthuis, 1981: 336 (references); Tan, 2004: 500, figures 137G, H; 140B (references).

MATERIAL EXAMINED

MU86, 91–103 m, (1); MU170, 102–92 m, (13); MU171, 105–100 m, (19); MU183, 138–177 m, (1); MU210, 86–90 m, (1); MU212, 163–200 m, (2); MU233, 165–189 m, (1); MUBV01, 112 m, (63); MUBV02, 318–330 m, (2); MUBV10, 332–344 m, (6); MUBV15, 148–135 m, (11); MUBV21, 107–109 m, (18).

Males: 8.26–13.61 mm, ovigerous females: 6.71–10.81 mm.

IDENTIFICATION

Our specimens agree well with the original description.

BIOLOGY

Species found on a variety of bottoms such as mud, muddy sand, mud with branched foraminifera, sandy mud, shelly mud, broken shells, coral or rock, at depths between 64 and 215 m. Ovigerous females have been previously recorded in February, March, May, July and November (Manning & Holthuis, 1981).

Our specimens were captured in depths from 86–90 to 332–344 m, in bottoms of coarse sand with mud and shell debris, muddy sand and sandy mud. Ovigerous females were collected in November and December.

Fig. 26. *Solenolambrus noordendei* (Capart, 1951), ovigerous female CL: 9.04 mm dorsal view, MU233.

GEOGRAPHIC DISTRIBUTION

West Africa from Mauritania (present work) to Angola (Manning & Holthuis, 1981).

REMARKS

Our records extend northwards the geographic distribution, from Senegal to Cape Blanc. They also broaden the bathymetric range of the species down to 322–344 m. The presence of ovigerous females also in December suggests that this species spawns throughout the year.

Genus *Spinolambrus* Tan & Ng, 2007

Spinolambrus notialis (Manning & Holthuis, 1981)
(Figure 27)

Parthenope notialis Manning & Holthuis, 1981: 331, figures 85, 86a–b.

Spinolambrus notialis: Tan, 2004: 524, figures 144A–B, 146B; Tan & Low, 2014: 96, figure 2B.

MATERIAL EXAMINED

MU131, 102–104 m, (1); MU186, 174 m, (1); MUBV21, 107–109 m, (1).

Female: 7.21 mm, ovigerous female: 10.08 mm.

IDENTIFICATION

Our specimens agree well with the original description.

BIOLOGY

Species recorded on bottoms of mud, sandy mud or sand, mostly mixed with broken shells, bryozoans, branched or foliate foraminifera, calcareous algae, corals and rocks. Bathymetric range from 18 to 162 m (Manning & Holthuis 1981: 335 as *Parthenope notialis*). Ovigerous females have been reported in February, March, May, June, July, September and November (Zariquiey Álvarez, 1968: 441 as *Parthenope macrochelos*; Manning & Holthuis, 1981: 335 as *Parthenope notialis*).

Our specimens were captured from 102–104 to 174 m, on coarse sand and muddy sand bottoms. Ovigerous females were collected in December.

GEOGRAPHIC DISTRIBUTION

West Africa from Mauritania (present work, see Remarks) to Angola (Manning & Holthuis, 1981: 335 as *Parthenope*

Fig. 27. *Spinolambrus notialis* (Manning & Holthuis, 1981), ovigerous female CL: 10.08 mm dorsal view, MU131.

notialis). Muñoz *et al.* (2012) reported this species from Guinea-Bissau.

REMARKS

This species was relocated by Tan & Ng (2007) in their new genus *Spinolambrus* erected to include some species of the subfamily Parthenopinae previously placed within the genera *Lambrus* and *Parthenope* from both the Atlantic and the Eastern Pacific.

Manning & Holthuis (1981) established the distribution range of this species at least from Senegal to Angola, inasmuch as the authors pointed out that most of the records of *S. macrochelos* (as *P. macrochelos*) from tropical West Africa were based on *S. notialis*. In consequence, they described the records of Maurin (1968; as *Lambrus macrocheles*) from the Western Sahara and Mauritanian waters as dubious, and a further taxonomic revision would assign them to *S. notialis* or *S. macrochelos*. The same occurs with the citation in Fransen (1991), although in this case Fransen referred to the specimens as '*Parthenope notialis/miersi*' [*Parthenope miersii* was synonymized with *S. macrochelos* (Tan, 2004)].

The southernmost distribution of *S. macrochelos* was confirmed by Tan & Low (2014) in Salé (Morocco) and the authors suggest that the distributions of *S. macrochelos* and *S. notialis* may overlap in North-west Africa.

Our record off Banc d'Arguin confirms the presence of this species in Mauritanian waters and slightly extends its bathymetric distribution.

The presence of ovigerous females in December confirms that this species spawns all the year round.

Superfamily PORTUNOIDEA Rafinesque, 1815

Family CARCINIDAE MacLeay, 1838

Genus *Liocarcinus* Stimpson, 1871

Liocarcinus corrugatus (Pennant, 1777)

(Figure 28A–C)

Cancer corrugatus Pennant, 1777: 5, pl. V figure 9.

Liocarcinus corrugatus: Manning & Holthuis, 1981: 84 (references).

MATERIAL EXAMINED

MUBVo8, 174–168 m, (2).

Male: 13.07 mm.

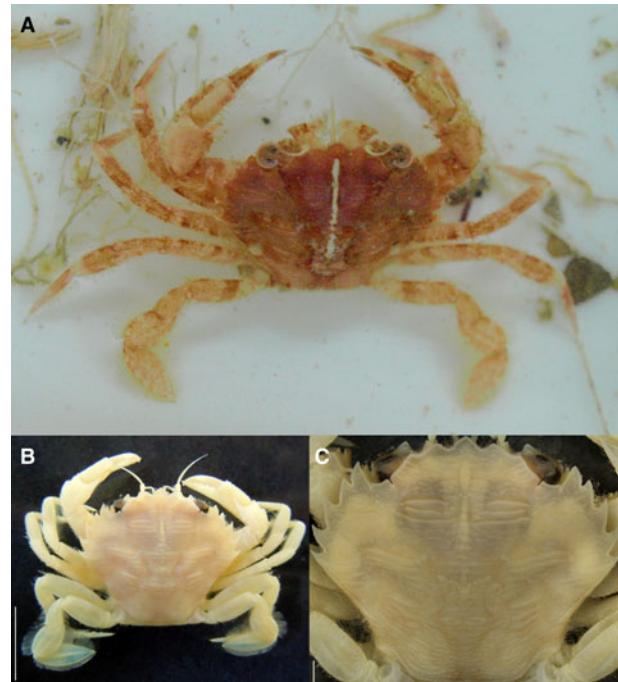

Fig. 28. *Liocarcinus corrugatus* (Pennant, 1777), male CL: 13.07 mm, MUBVo8: (A) dorsal view; (B) same, in ethanol; (C) dorsal carapace, in alcohol. Scale bars: B, 1 cm; C, 1 mm.

IDENTIFICATION

Our specimen agrees well with those described by Zariquey Álvarez (1968) and González-Gurriarán & Méndez (1986).

BIOLOGY

Mainly reported on coarse soft bottoms such as gravel, coarse sand, sandy mud, muddy sand and maerl beds (d'Udekem d'Acoz, 1999; as *Polybius* (*Necora*) *corrugatus*; El Lakhach *et al.*, 2012), but also recorded on rocks and in *Posidonia oceanica* (Linnaeus) Delile, 1813 meadows (Pipitone & Arculeo, 2003; as *Polybius corrugatus*; Pipitone & Vaccaro, 2011). Depth records from 5–10 m (Pipitone & Arculeo, 2003; as *Polybius corrugatus*) to 147 m (d'Udekem d'Acoz, 1999; as *Polybius* (*Necora*) *corrugatus*). Ovigerous females reported from November to January, March, May, June and July (Zariquey Álvarez, 1968; as *Macropipus corrugatus*; García Raso, 1984).

Only one male was captured during the MAURIT surveys, between 168 and 174 m.

GEOGRAPHIC DISTRIBUTION

East Atlantic, from the Orkney Islands to Angola, including the Azores, Madeira, Canary and Cape Verde Islands; and Mediterranean Basin (d'Udekem d'Acoz, 1999: 219) (see Remarks).

Further records in the literature (Abelló *et al.*, 2002; García Raso & Manjón-Cabeza, 2002; Pipitone & Arculeo, 2003; as *Polybius corrugatus*; Ateş *et al.*, 2006; García-Muñoz *et al.*, 2008; Pipitone & Vaccaro, 2011; El Lakhach *et al.*, 2012; Muñoz *et al.*, 2012) fit well within this geographic distribution.

REMARKS

Liocarcinus corrugatus was also reported from many localities in the Indo-Pacific, but d'Udekem d'Acoz (1999) stated that

all these records probably belong to one or more closely allied species. Ng *et al.* (2001) followed d'Udekem d'Acoz and excluded *L. corrugatus* from the checklist of brachyurans from Taiwan, but later Yaldwin & Webber (2011) included this species in the Decapoda checklist of New Zealand.

Our data slightly increase the bathymetric range previously reported in the literature.

Family GERYONIDAE Colosi, 1923
Genus *Chaceon* Manning & Holthuis, 1989
Chaceon maritae (Manning & Holthuis, 1981)
(Figure 29A, B)

Geryon maritae Manning & Holthuis, 1981: 112, figures 24a, 25, 26.

MATERIAL EXAMINED

MU01, 817–820 m, (2); MU15, 670–675 m, (1); MU17, 818–861 m, (3); MU18, 519–402 m, (40); MU19, 1222–1218 m, (1); MU23, 532–415 m, (2); MU26, 744 m, (1); MU33, 741–736 m, (2); MU46, 848–847 m, (3); MU48, 1239–1218 m, (1); MU55, 1310–1218 m, (1); MU56, 1091–1159 m, (1); MU62, 1236–1244 m, (1); MU67, 1381–1390 m, (1); MU68, 1136–1146 m, (5); MU70, 755–801 m, (3); MU73, 1330–1284 m, (1); MU79, 554–576 m, (5); MU126, 668–826 m, (2); MU177, 584–580 m, (9); MU182, 726 m, (1); MU188, 627 m, (1); MU243, 827–850 m, (3); MU267, 673–670 m, (16); MUBV03, 528–538 m, (1); MUBV13, 493–517 m, (1).
Males: 23.63–68.34 mm; females: 21.94–77.95 mm.

IDENTIFICATION

Our specimens agree well with the original description.

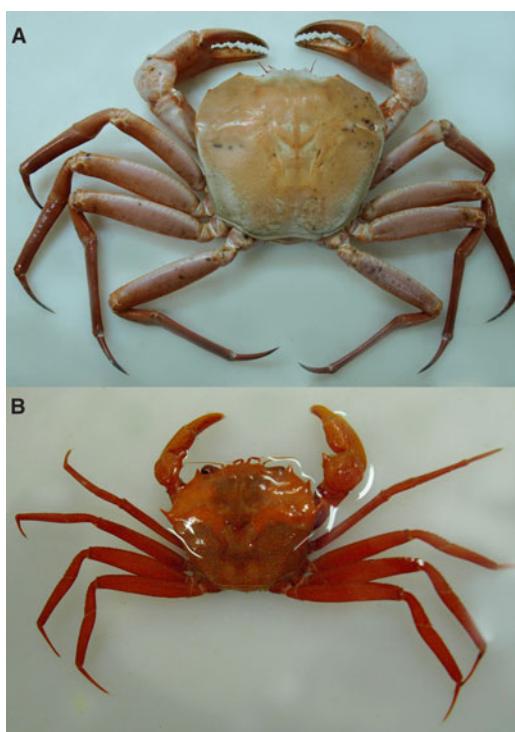

Fig. 29. *Chaceon maritae* (Manning & Holthuis, 1981): (A) adult dorsal view, MU243; (B) juvenile CL: 21.94 mm dorsal view, MU177.

BIOLOGY

Species inhabiting bottoms of mud, sandy mud and corals at depths from 100–300 m (Manning & Holthuis, 1981; as *Geryon maritae*) to 1994 m (Le Roux, 2001).

Although several works focus on the population dynamics of *C. maritae* for fishing purposes (Gaertner & Laloé, 1986; Melville Smith, 1988; Le Roux, 2001), surprisingly, none of them include data about the spawning period for this species.

Our specimens were collected between 402–519 and 1381–1390 m on muddy sand and sandy mud bottoms.

GEOGRAPHIC DISTRIBUTION

West Africa from the Western Sahara to Namibia (Manning & Holthuis, 1981; d'Udekem d'Acoz, 1999) (see Remarks). Le Roux (2001) reported this species off Namibia and Muñoz *et al.* (2012) from Guinea-Bissau.

REMARKS

Species occurrence in the Canary Islands (González *et al.*, 1996) needs confirmation (d'Udekem d'Acoz, 1999).

Fig. 30. *Bathynectes piperitus* Manning & Holthuis, 1981, male CL: 13.60 mm dorsal view, MU123.

Males: 13.60–55.06 mm; females: 13.13–41.98 mm; ovigerous females: 35.52–40.72 mm.

IDENTIFICATION

Our specimens agree well with the original description.

BIOLOGY

Collected on mud, muddy sand, sand and gravel bottoms and on corals, in depths from 200 to 628 m. Ovigerous females recorded from February to June (Manning & Holthuis, 1981).

Our specimens were captured at depths from 260–353 to 618–850 m on sand and sandy mud bottoms. Ovigerous females were collected in November and December.

GEOGRAPHIC DISTRIBUTION

Known in West Africa, from the Cape Verde Islands (Manning & Holthuis, 1981) and Mauritania (present work) to Namibia (Macpherson, 1991), the species is probably present up to Western Saharan waters (see Remarks). Henriksen (2009) reports this species off Gabon.

REMARKS

Specimens of *Bathynectes piperitus* have been largely identified under the name of the European and Mediterranean *B. maravigna* (Prestandrea, 1839). The differences between both species were summarized by Manning & Holthuis (1981). Our Mauritanian record of *B. piperitus* supports the opinion expressed by Manning & Holthuis (1981) that the records of *B. superbus* (=*B. maravigna*) from Cape Bojador (Western Sahara) and Mauritania, given by Maurin (1968), and those of *Bathynectes*, given by Filhol (1885), may in fact be referable to *B. piperitus*.

Our records of ovigerous females determine a spawning period between November and June.

Genus *Macropipus* Prestandrea, 1833
Macropipus rugosus (Doflein, 1904)
 (Figure 31)

Males: 7.39–32.41 mm, females: 7.43–24.95 mm, ovigerous females: 18.49–23.43 mm.

Fig. 31. *Macropipus rugosus* (Doflein, 1904), ovigerous female CL: 23.43 mm dorsal view, MUBV01.

IDENTIFICATION

Our specimens agree well with the original description and with the notes provided by Guinot (1961: 2).

BIOLOGY

Bottoms of mud, muddy sand, sand, broken shells, foraminifera, bryozoans and also on calcareous algae and rocks, at depths from 5 to 400 m. Ovigerous females previously recorded in June and September (Manning & Holthuis, 1981: 86).

Our specimens were captured between 81–84 and 210–257 m on muddy sand, sandy mud, coarse muddy sand, sand and on coarse sand with shell debris bottoms. Ovigerous females were collected in November and December.

GEOGRAPHIC DISTRIBUTION

West Africa from Western Sahara to Angola, including São Tomé and Príncipe Islands (Manning & Holthuis, 1981: 86). Further records can be found at Nigeria, Príncipe and Congo (Henriksen, 2009) and Guinea-Bissau (Muñoz et al., 2012).

REMARKS

Ovigerous females were reported for the first time at the end of the year, indicating that this species spawns in the second half of the year.

BIOLOGY

This species was captured on coral, at depths from 160 to 300 m; ovigerous females were reported from July and August (label with paratypes ICMDoooo031, ICMDoooo032 and ICMDoooo033; Guinot & Macpherson, 1988: 744).

Our specimens were found on sandy bottoms and hidden in the holes of large stones hauled up in the net, at depths from 100–105 to 332–344 m. The ovigerous female was captured in December.

GEOGRAPHIC DISTRIBUTION

Western Africa in Mauritania (present work) and Namibia (Guinot & Macpherson, 1988) (see Remarks).

REMARKS

Monodaeus cristulatus has only been previously reported from Namibian coasts (28° – 29° S). Following Guinot & Macpherson (1988), the closest species is *Monodaeus couchii*, previously reported from various localities of NW Africa (Manning & Holthuis, 1981), including Mauritanian waters (Milne-Edwards & Bouvier, 1900; Anadon, 1981; Fransen, 1991). We have compared our material with specimens of *M. cristulatus* from Namibia and with samples of *M. couchii* from the

Western Mediterranean, Gulf of Cádiz and Moroccan Atlantic coasts (see comparative material examined). After these comparisons, we included our specimens in *M. cristulatus*, due to the presence of a dorsal crest on P₂–P₅ meri and a proximal protuberance on P₂–P₄ dorsal carpi (Figure 33E–H), which are absent in *M. couchii* (Figure 33A–D). In juveniles of *M. cristulatus* the specific characters are not clearly developed (Guinot & Macpherson, 1988), which hinders species separation when studying isolated specimens. However, checking a series of different features on specimens of various sizes allows for accurate identification.

The possible misidentification of the two species and our findings of *Monodaeus cristulatus* in Mauritanian waters point to a need for a revision of the records of *M. couchii* south of Cape Blanc. Our records suggest that *M. cristulatus* can be found along the West African coast between Banc d'Arguin, Mauritania and Namibia.

Males: 6.61–20.68 mm; females: 6.30–11.39 mm.

IDENTIFICATION

Our specimens agree well with the description provided by Türkay (1975: 105) and with the comments and pictures after Giacobbe & Spano (2006).

BIOLOGY

Collected on gravel, shell, sand, sandy mud and muddy bottoms, the species is also recorded on bottoms of rock with gorgonians, sponges, calcareous algae and kelp, and coral reefs (Manning & Holthuis, 1981: 248; d'Udekem d'Acoz, 1999: 250; Giacobbe & Spano, 2006). Depth records range between 10 m (d'Udekem d'Acoz, 1999: 250) and 620–621 m (Abelló et al., 2002). Ovigerous females were collected only in March (Manning & Holthuis, 1981).

Fig. 34. *Euchirograpsus liguricus* H. Milne-Edwards, 1853, male CL: 20.68 mm dorsal view, MUBV14.

Our material was collected at 281–300 and 311 m. The species was caught in a ghost net hauled with the Lofoten trawl and in the holes of a large stone captured with the beam trawl.

GEOGRAPHIC DISTRIBUTION

East Atlantic from West Portugal to Namibia including the Azores, Madeira, Savage, Canary and Cape Verde Islands; Western and Central Mediterranean Sea (d'Udekem d'Acoz, 1999; Giacobbe & Spano, 2006). Abelló et al. (2002) report this species from the Eastern Alborán Sea.

DISCUSSION

A total of 10,514 brachyuran specimens were studied from waters off Mauritania at depths from 79 to 1867 m, comprising 33 species belonging to 17 families and 24 genera. The brachyuran diversity found in recent works carried out with a similar methodology on West African coasts is slightly lower than the values of our study. García Raso (1996) reported 31 brachyuran species from the Ibero-Moroccan Bay and adjacent waters at depths from 137 to 2142 m; Muñoz et al. (2012) listed 44 brachyuran species off Guinea-Bissau at depths between 20 and 1000 m, of which only 24 were found deeper than 80 m; and Macpherson (1991) included 21 brachyuran species in Namibian waters from 100 to 1000 m.

The most abundant species so far was *Macropipus rugosus* (89%), mainly due to the high number of specimens captured at two stations off Nouakchott (MU101, 2304 specimens; MU154, 4819 specimens). However, the remaining stations showed similar abundances to those reported for this species in Guinea-Bissau (Muñoz et al., 2012), Guinea (Le Loeuf, 1993) and the Gulf of Guinea (Henriksen, 2009). Conversely, the following three species, *Atelecyclus rotundatus*, *Ethusa rosacea* and *Macropodia longipes*, were represented by only one specimen each. The low abundance of *A. rotundatus* is probably explained by its burrowing behaviour (González-Gurriarán & Méndez, 1986; S. de Matos-Pita, unpublished data), which hinders or prevents the capture of the species by the trawl. *Macropodia longipes*, although reported from the Gulf of Gascogne to the Cape Verde Islands and the Mediterranean Sea, has only been recorded in Mauritanian waters on the Banc d'Arguin (Forest, 1978, as *Macropodia tenuirostris longipes*). *Ethusa rosacea* and *M. longipes* are both considered as rare species because they were seldom reported and always in very low abundance (Monod, 1956; Manning & Holthuis, 1981; Henriksen, 2009).

Different patterns are observed for the latitudinal distribution of the species in the area studied. Eleven species, *Homola barbata*, *Paromola cuvieri*, *Acanthocarpus brevispinis*, *Goneplax barnardi*, *Inachus angolensis*, *Macropodia gilsoni*, *M. macrocheles*, *Chaceon maritae*, *Bathynectes piperitus*, *Macropipus rugosus* and *Monodaeus cristulatus*, are evenly distributed along most of the Mauritanian coast. Three species, *Medorippe lanata*, *Eurynome aspera* and *Distolambrus maltzami*, were sampled only north of Cape Timiris, and another six, *Ethusa rosacea*, *Pisa armata*, *Inachus aguiarii*, *Macropodia hesperia*, *M. longipes* and *Euchirograpsus liguricus* were only captured between Cape Timiris and the Senegalese border. *Calappa pelii*, *Ethusa rugulosa*, *Goneplax rhomboides*, *Pseudomyra mbizi*, *Inachus*

grallator, *I. nanus*, *Solenolambrus noordendei* and *Spinolambrus notialis* were scarcely sampled north and south of Cape Timiris. Finally, another five species, *Cymonomus granulatus*, *Atelecyclus rotundatus*, *Ebalia nux*, *Inachus leptochirus* and *Liocarcinus corrugatus*, were sampled only off Cape Blanc.

Analysis of the geographic distribution reveals three different contingents within the Mauritanian brachyuran fauna. The main zoogeographic group (18 species, 54.5%) is composed of species distributed along the West African coast, mainly in the tropical region. Within this group, 14 species, *A. brevispinis*, *C. pelii*, *E. rosacea*, *E. rugulosa*, *G. barnardi*, *P. mbizi*, *I. angolensis*, *M. gilsoni*, *M. macrocheles*, *S. noordendei*, *S. notialis*, *C. maritae*, *B. piperitus* and *M. rugosus* were mostly evenly reported from the Western Sahara and Mauritania to Angola and Namibia. Two species, *I. nanus* and *M. hesperiae*, were reported between Mauritania and the Gulf of Guinea. *Inachus grallator*, previously reported between the Gulf of Guinea and Namibia, and *M. cristulatus*, only known from the type locality (Namibia), have a discontinuous latitudinal distribution and are now both recorded in Mauritanian waters. Species with a restricted and/or discontinuous distribution in tropical West Africa have been reported in recent decades (Manning & Holthuis, 1981; Macpherson, 1991), but a more complete sampling effort in West African waters will certainly extend their known distribution.

The second zoogeographic group (10 species, 30.3%) is represented by species widely distributed in the Lusitanian province, including the Mediterranean Sea. The southern limit of the Lusitanian province was recently established at Cape Juby (south Morocco) by Briggs & Bowen (2012), but set up at Cap Vert (Senegal) by Briggs (1995). *Macropodia longipes* is the only species with a strictly Lusitanian distribution, while the distributional limits of the remaining species extend further northwards or southwards. Five species range southwards to Guinea (*I. aguiarii*), Angola (*D. maltzami*), Namibia (*E. liguricus*), South Africa (*H. barbata*) and even into the Indian Ocean up to Mozambican waters (*M. lanata*). Another four species, *C. granulatus*, *G. rhomboides*, *E. nux* and *I. leptochirus*, extend their distribution area to northern European seas.

Finally, the third zoogeographic group includes five species (15%) widely distributed in the E Atlantic and Mediterranean, with records from northern European seas southwards to Angola (*P. armata* and *L. corrugatus*), South Africa (*P. cuvieri* and *A. rotundatus*) and even to Durban in the West Indian Ocean (*E. aspera*).

In this region, the affinity with Atlantic-Mediterranean fauna was previously reported for different taxa: Porifera (van Soest, 1993), Hydrozoa (Ansín Agis *et al.*, 2001), Bryozoa (Aristegui & Cruz, 1986) and Echinodermata (Hernández *et al.*, 2013; Calero *et al.*, in preparation). For all these taxa, the Canary Current was highlighted as the main means of larval dispersion southwards, also enabling the presence of typical boreal species, such as *C. granulatus*, *G. rhomboides*, *E. nux* and *I. leptochirus*, in NW African waters. Conversely, the presence of tropical species in Mauritania (*C. pelii*, *E. rosacea*, *E. rugulosa*, *G. barnardi*, *P. mbizi*, *I. angolensis*, *I. grallator*, *I. nanus*, *M. gilsoni*, *M. hesperiae*, *M. macrocheles*, *S. noordendei*, *S. notialis*, *C. maritae*, *B. piperitus* and *M. rugosus*) is more difficult to explain because of dominant current systems precluding their dispersion northwards (Aristegui & Cruz, 1986; Hernández *et al.*, 2013). However, a thin surface coastal current flowing northwards along the Gabonese and Congolese coasts (Stramma & Schott, 1999), and the so-called ‘Mauritania Current’ (Stramma & Schott, 1999) flowing northwards in summer and autumn between Cap Vert and Cape Blanc (Pastor *et al.*, 2008), probably facilitate the northwards dispersion of tropical species along the West African coastline. The importance of small currents in the dispersion of species was highlighted by Briggs (1995) as the main way of successfully transporting species in an opposite direction to that of the main flow across the Tropical Pacific and the Atlantic Oceans.

There are three bathymetrical groups of brachyurans in Mauritanian waters. The first group includes 13 species collected exclusively on the shelf (80–200 m; *C. pelii*, *M. lanata*, *P. mbizi*, *P. armata*, *I. aguiarii*, *I. nanus*, *M. gilsoni*, *M. hesperiae*, *M. longipes*, *E. aspera*, *D. maltzami*, *S. notialis* and *L. corrugatus*); the second is represented by nine species collected both on the shelf and upper slope (80–400 m; *H. barbata*, *E. rugulosa*, *G. rhomboides*, *I. angolensis*, *I. grallator*, *M. cristulatus*, *P. mbizi*, *E. rugulosa*, *M. gilsoni*, *I. nanus*, *S. notialis*, *L. corrugatus*, *P. armata*, *I. aguiarii* and *M. hesperiae*).

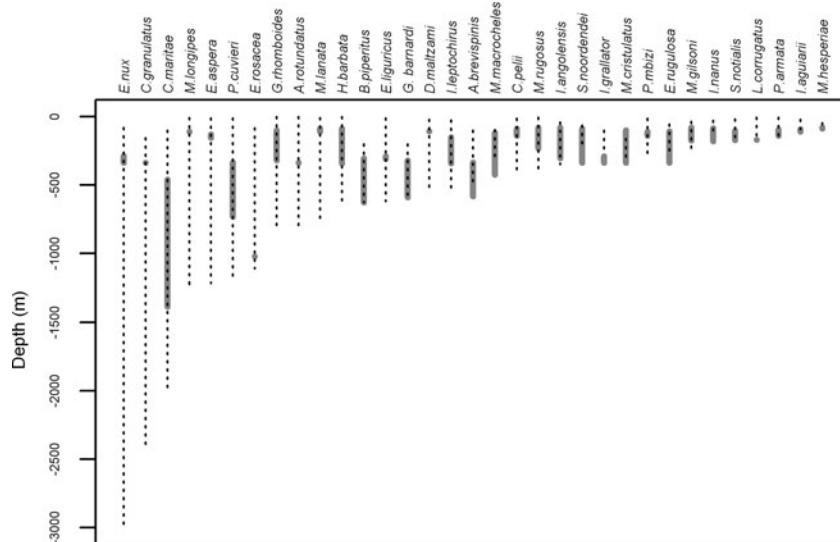

Fig. 35. Depth records of brachyuran species. Translucent continuous line from MAURIT surveys, dotted line from the literature.

leptocheirus, *M. macrocheles*, *S. noordendei*, *M. rugosus* and *M. cristulatus*); and the third accounts for nine species exclusively recorded along the upper slope (300–700 m; *P. cuvieri*, *C. granulatus*, *A. brevispinis*, *A. rotundatus*, *G. barnardi*, *E. nux*, *I. grallator*, *B. piperitus* and *E. liguricus*) (Figure 35). In addition, *C. maritae* was collected on the upper and middle slope (460–1385 m) and *E. rosacea* only at 1024 m.

Despite the increase in decapod diversity with depth described in several regions, peaking between 1000 and 2000 m (see Muñoz *et al.*, 2012 for references), brachyuran crabs do not seem to follow this general trend in Mauritanian waters.

Our results emphasize the highest specific richness of the deep shelf (22 species, 66.66%) and its drastic reduction beyond 700 m (two species, 6.06%). The importance of crustaceans and at least of some brachyuran families (Inachidae, Portunidae, Parthenopidae and Dorippiidae) on the Mauritanian deep shelf was previously pointed out by Duineveld *et al.* (1993). A similar bathymetric pattern was described for the brachyurans off Guinea-Bissau by Muñoz *et al.* (2012), clearly dominated by shelf species and only three typical deep species, which also include *C. maritae*. Soto (1991) also reported a strong reduction in species diversity beyond 500 and 700 m in the Straits of Florida. This reduction was related to the high trophic level of brachyurans and the more limited food availability in deep waters (Escobar-Briones *et al.*, 2008).

Analysis of bathymetric ranges shows that in Mauritanian waters all but three of the studied species are stenobathic, with depth ranges narrower than 300 m (Menzies *et al.*, 1973; Pielou, 1992). Only *P. cuvieri*, *C. maritae* and *B. piperitus* (depth ranges of 322, 397 and 925 m, respectively) can be considered eurybathic species. However, considering data from the literature, only 13 of the studied species are stenobathic (*E. rugulosa*, *P. mbizi*, *P. armata*, *I. aguiarii*, *I. grallator*, *I. nanus*, *M. gilsoni*, *M. hesperiae*, *M. macrocheles*, *S. noordendei*, *S. notialis*, *L. corrugatus* and *M. cristulatus*). In consequence, the Mauritanian brachyuran fauna is dominated by eurybathic species, a feature also shared with the brachyurans of the Straits of Florida (Soto, 1991).

ACKNOWLEDGEMENTS

The authors wish to thank all those who made possible the study of the material captured in Maurit surveys, especially Dr Ana Ramos and the Spanish Institute of Oceanography (IEO). We thank Drs Félix Pérez and Pere Abelló from the Instituto de Ciencias Marinas (ICM-CSIC) for their invaluable help and patience in locating some of the comparison material checked here. We would also like to thank Luis Miguel Agudo for providing the map.

FINANCIAL SUPPORT

This work was undertaken within the framework of the ECOAFRIK project and was partially funded by the Galician government (Spain, Project Ref. 10MMA602020PR) and by the 'MAVA Fondation pour la nature' (MAVA contract 12/87 AO C4/2012). This is ECOAFRIK publication number 5.
