

Results: There were 1,028 respondents to the survey. The respondents primarily were male, frontline personnel with >15 years of experience. Only 63% of respondents indicated they had received either theoretical or practical training to work in a contaminated environment. Of those that had received any training, 61% indicated they had received “hands on” or practical training. In regards to identifying a possibly contaminated scene, 82% indicated they had received some training. Only 42% had received training on symptoms of nerve agent exposure, 37% on symptoms of blister agent exposure, and 46% on symptoms of asphyxiants. In regard to treating victims of chemical agents, 32% had received training regarding nerve agents, and 30% regarding blister agents. Only 31% of all respondents had received training regarding the detection of radiation.

Conclusions: Chemical, biological, radiological, and nuclear events have unique hazards and require specific education and training. As assessed with this survey, Canadian prehospital providers do not uniformly receive the training to identify and work in contaminated environments.

Medical Care within the Hot Zone: An Innovative Concept in Vienna during the EURO08

Andreas Ziegler

EMS, City of Vienna, Parndorf, Austria

Introduction: The response to hazardous materials or chemical, biological, radiological, nuclear (CBRN) incidents typically consists of: (1) cordons regulating access into and egress from designated zones; and (2) use of appropriate personal protective equipment. In most systems emergency medical services (EMS) will stay outside of the “hot zone”. The patient will be rescued by the fire service and, after some gross decontamination, handed over. As mass gatherings are regarded as high-risk events, this system was used in Vienna during the Euro08 and augmented by: (1) casualty decontamination units (seven parallel lines for stretcher decontamination, located before triage); (2) a rapid intervention group for medical care in the hot zone (25 medical personnel), responsible for triage, life support (airway, breathing, bleeding), and antidote therapy; and (3) a joint CBRN incident command for close cooperation with detection units.

Methods: After a review of the available open-source literature, a risk analysis was performed and the tactical concept described above was developed with cooperation of all involved services. Special training was performed for all members of the aforementioned units.

Results: As the concept was not tested by an actual emergency, the following observations can be made: (1) readiness of the units could be successfully maintained during the EURO08; (2) the chosen equipment was experienced as appropriate; (3) several minor cases corroborated the risk analysis; and (4) manpower and training requirements were considerable.

Conclusions: While it is possible to perform medical care within the hot zone, concepts are rarely tested in reality and the necessary efforts raise the question of proportionality.

Fifteen Years since the Tokyo Subway Attack and Development of Chemical, Biological, Radiological, Nuclear, or Explosive Terrorist Countermeasures in Japan

Tetsu Okumura

Saga University, Saga, Japan

Introduction: Although 15 years have passed since the Tokyo subway attack, it was the preparations for the Kyushu-Okinawa G8 summit (2000) five years thereafter that catalyzed the development of countermeasures and policy against chemical, biological, radioactive, nuclear, or explosive (CBRNE) threats in Japan.

Report: No substantial progress was made for five years after the subway attack. Preparedness for the Kyushu-Okinawa G8 Summit included promulgation of the Civil Protection Law (2004), which codified the responses to CBRNE terrorist attacks, and consequently, the effectiveness with which the countermeasures against CBRNE terrorism acts could be deployed at a national level. Countermeasures included the establishment of a CBRNE task force, syndromic surveillance programs, and the stockpiling of antidotes, antitoxins, and antibiotics. Decontamination facilities were introduced throughout Japan.

Conclusions: Preparedness for the summit facilitated recognition of the need for medical countermeasures against CBRNE threats to protect healthcare providers in Japan. In the 15 years since the Tokyo Subway Attack, the measures implemented in the last five years have been most effective. However, future challenges include the promotion of civilian awareness, inter-agency collaboration, and increasing the mutual-aid capacity of local communities.

Responsibility and Methods for Detection of Chemicals and Radioactive Substances and Decontamination

Andreas Ziegler

Emergency Medical Services, City of Vienna, Parndorf, Austria

Introduction: The response to incidents with chemical and radioactive substances has been shaped primarily by firefighters' experiences with hazardous material (HAZMAT) accidents. Globally, HAZMAT tactics consist of the main elements of: (1) appropriate use of personal protective equipment; and (2) cordons regulating access into and egress from designated zones. Detection and casualty decontamination are far less uniformly organized.

Methods: Review and analysis of open-source (medical- and first responder-oriented) English and German lan-
